

MICROCHIP

# PIC24FJ128GB204 FAMILY

## 28/44-Pin, General Purpose, 16-Bit Flash Microcontrollers with Cryptographic Engine, ISO 7816, USB On-The-Go and XLP Technology

### Cryptographic Engine

- AES Engine with 128,192 or 256-Bit Key
- Supports ECB, CBC, OFB, CTR and CFB128 modes
- DES/Triple DES (TDES) Engine: Supports 2-Key and 3-Key EDE or DED TDES
- Supports up to Three Unique Keys for TDES
- Programmatically Secure
- True Random Number Generator
- Pseudorandom Number Generator
- Non-Readable, On-Chip, OTP Key Storages

### Universal Serial Bus Features

- USB v2.0 On-The-Go (OTG) Compliant
- Dual Role Capable; can Act as Either Host or Peripheral
- Low-Speed (1.5 Mb/s) and Full-Speed (12 Mb/s) USB Operation in Host mode
- Full-Speed USB Operation in Device mode
- High-Precision PLL for USB
- USB Device mode Operation from FRC Oscillator:
  - No crystal oscillator required
- Supports up to 32 Endpoints (16 bidirectional):
  - USB module can use any RAM locations on the device as USB endpoint buffers
- On-Chip USB Transceiver
- Supports Control, Interrupt, Isochronous and Bulk Transfers
- On-Chip Pull-up and Pull-Down Resistors

### Extreme Low-Power Features

- Multiple Power Management Options for Extreme Power Reduction:
  - VBAT allows the device to transition to a backup battery for the lowest power consumption with RTCC
  - Deep Sleep allows near total power-down, with the ability to wake-up on internal or external triggers
  - Sleep and Idle modes selectively shut down peripherals and/or core for substantial power reduction and fast wake-up
  - Doze mode allows CPU to run at a lower clock speed than peripherals
- Alternate Clock modes allow On-the-Fly Switching to a Lower Clock Speed for Selective Power Reduction
- Extreme Low-Power Current Consumption for Deep Sleep:
  - WDT: 270 nA @ 3.3V typical
  - RTCC: 400 nA @ 32 kHz, 3.3V typical
  - Deep Sleep current: 40 nA, 3.3V typical

# PIC24FJ128GB204 FAMILY

---

## Analog Features

- 10/12-Bit, 12-Channel Analog-to-Digital (A/D) Converter:
  - Conversion rate of 500 ksp/s (10-bit), 200 ksp/s (12-bit)
  - Conversion available during Sleep and Idle
- Three Rail-to-Rail, Enhanced Analog Comparators with Programmable Input/Output Configuration
- Three On-Chip Programmable Voltage References
- Charge Time Measurement Unit (CTMU):
  - Used for capacitive touch sensing, up to 12 channels
  - Time measurement down to 100 ps resolution
  - Operation in Sleep mode

## Peripheral Features

- Up to Five External Interrupt Sources
- Peripheral Pin Select (PPS); Allows Independent I/O Mapping of many Peripherals
- Five 16-Bit Timers/Counters with Prescaler:
  - Can be paired as 32-bit timers/counters
- Six-Channel DMA supports All Peripheral modules:
  - Minimizes CPU overhead and increases data throughput
- Six Input Capture modules, each with a Dedicated 16-Bit Timer
- Six Output Compare/PWM modules, each with a Dedicated 16-Bit Timer
- Enhanced Parallel Master/Slave Port (EPMP/EPSP)
- Hardware Real-Time Clock/Calendar (RTCC):
  - Runs in Sleep, Deep Sleep and VBAT modes
- Three 3-Wire/4-Wire SPI modules:
  - Support four Frame modes
  - Variable FIFO buffer
  - I<sup>2</sup>S mode
  - Variable width from 2-bit to 32-bit
- Two I<sup>2</sup>C™ modules Support Multi-Master/Slave mode and 7-Bit/10-Bit Addressing
- Four UART modules:
  - Support RS-485, RS-232 and LIN/J2602
  - On-chip hardware encoder/decoder for IrDA®
  - Smart Card ISO 7816 support on UART1 and UART2 only:
    - T = 0 protocol with automatic error handling
    - T = 1 protocol
    - Dedicated Guard Time Counter (GTC)
    - Dedicated Waiting Time Counter (WTC)
  - Auto-wake-up on Auto-Baud Detect (ABD)
  - 4-level deep FIFO buffer
- Programmable 32-Bit Cyclic Redundancy Check (CRC) Generator
- Digital Signal Modulator provides On-Chip FSK and PSK Modulation for a Digital Signal Stream
- High-Current Sink/Source (18 mA/18 mA) on All I/O Pins
- Configurable Open-Drain Outputs on Digital I/O Pins
- 5.5V Tolerant Inputs on Most Pins

## High-Performance CPU

- Modified Harvard Architecture
- Up to 16 MIPS Operation @ 32 MHz
- 8 MHz Internal Oscillator:
  - 96 MHz PLL option
  - Multiple clock divide options
  - Run-time self-calibration capability for maintaining better than ±0.20% accuracy
  - Fast start-up
- 17-Bit x 17-Bit Single-Cycle Hardware Fractional/Integer Multiplier
- 32-Bit by 16-Bit Hardware Divider
- 16 x 16-Bit Working Register Array
- C Compiler Optimized Instruction Set Architecture (ISA)
- Two Address Generation Units (AGUs) for Separate Read and Write Addressing of Data Memory

## Special Microcontroller Features

- Supply Voltage Range of 2.0V to 3.6V
- Two On-Chip Voltage Regulators (1.8V and 1.2V) for Regular and Extreme Low-Power Operation
- 20,000 Erase/Write Cycle Endurance Flash Program Memory, Typical
- Flash Data Retention: 20 Years Minimum
- Self-Programmable under Software Control
- Programmable Reference Clock Output
- In-Circuit Serial Programming™ (ICSP™) and In-Circuit Emulation (ICE) via 2 Pins
- JTAG Programming and Boundary Scan Support
- Fail-Safe Clock Monitor (FSCM) Operation:
  - Detects clock failure and switches to on-chip, Low-Power RC Oscillator
- Power-on Reset (POR), Power-up Timer (PWRT) and Oscillator Start-up Timer (OST)
- Separate Brown-out Reset (BOR) and Deep Sleep Brown-out Reset (DSBOR) Circuits
- Programmable High/Low-Voltage Detect (HLVD)
- Flexible Watchdog Timer (WDT) with its Own RC Oscillator for Reliable Operation
- Standard and Ultra Low-Power Watchdog Timers (ULPW) for Reliable Operation in Standard and Deep Sleep modes

## TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at [docerrors@microchip.com](mailto:docerrors@microchip.com). We welcome your feedback.

### Most Current Data Sheet

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Web site at:

<http://www.microchip.com>

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS30000000A is version A of document DS30000000).

### Errata

An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

- Microchip's Worldwide Web site; <http://www.microchip.com>
- Your local Microchip sales office (see last page)

When contacting a sales office, please specify which device, revision of silicon and data sheet (include literature number) you are using.

### Customer Notification System

Register on our web site at [www.microchip.com](http://www.microchip.com) to receive the most current information on all of our products.

**NOTES:**

## 1.0 DEVICE OVERVIEW

This document contains device-specific information for the following devices:

- PIC24FJ64GB202      • PIC24FJ128GB202
- PIC24FJ64GB204      • PIC24FJ128GB204

The PIC24FJ128GB204 family expands the capabilities of the PIC24F family by adding a complete selection of Cryptographic Engines, ISO 7816 support and I<sup>2</sup>S support to its existing features. This combination, along with its ultra low-power features, Direct Memory Access (DMA) for peripherals and USB On-The-Go, make this family the new standard for mixed-signal PIC® microcontrollers in one economical and power-saving package.

## 1.1 Core Features

### 1.1.1 16-BIT ARCHITECTURE

Central to all PIC24F devices is the 16-bit modified Harvard architecture, first introduced with Microchip's dsPIC® Digital Signal Controllers (DSCs). The PIC24F CPU core offers a wide range of enhancements, such as:

- 16-bit data and 24-bit address paths with the ability to move information between data and memory spaces
- Linear addressing of up to 12 Mbytes (program space) and 32 Kbytes (data)
- A 16-element Working register array with built-in software stack support
- A 17 x 17 hardware multiplier with support for integer math
- Hardware support for 32 by 16-bit division
- An instruction set that supports multiple addressing modes and is optimized for high-level languages, such as 'C'
- Operational performance up to 16 MIPS

### 1.1.2 XLP POWER-SAVING TECHNOLOGY

The PIC24FJ128GB204 family of devices introduces a greatly expanded range of power-saving operating modes for the ultimate in power conservation. The new modes include:

- Retention Sleep with essential circuits being powered from a separate low-voltage regulator
- Deep Sleep without RTCC for the lowest possible power consumption under software control
- VBAT mode (with or without RTCC) to continue limited operation from a backup battery when VDD is removed

Many of these new low-power modes also support the continuous operation of the low-power, on-chip Real-Time Clock/Calendar (RTCC), making it possible for an application to keep time while the device is otherwise asleep.

Aside from these new features, PIC24FJ128GB204 family devices also include all of the legacy power-saving features of previous PIC24F microcontrollers, such as:

- On-the-Fly Clock Switching, allowing the selection of a lower power clock during run time
- Doze Mode Operation, for maintaining peripheral clock speed while slowing the CPU clock
- Instruction-Based Power-Saving Modes, for quick invocation of Idle and the many Sleep modes

### 1.1.3 OSCILLATOR OPTIONS AND FEATURES

All of the devices in the PIC24FJ128GB204 family offer five different oscillator options, allowing users a range of choices in developing application hardware. These include:

- Two Crystal modes
- Two External Clock (EC) modes
- A Phase-Locked Loop (PLL) frequency multiplier, which allows clock speeds of up to 32 MHz
- A Fast Internal Oscillator (FRC) – Nominal 8 MHz output with multiple frequency divider options and automatic frequency self-calibration during run time
- A separate Low-Power Internal RC Oscillator (LPRC) – 31 kHz nominal for low-power, timing-insensitive applications.

The internal oscillator block also provides a stable reference source for the Fail-Safe Clock Monitor (FSCM). This option constantly monitors the main clock source against a reference signal provided by the internal oscillator and enables the controller to switch to the internal oscillator, allowing for continued low-speed operation or a safe application shutdown.

### 1.1.4 EASY MIGRATION

Regardless of the memory size, all devices share the same rich set of peripherals, allowing for a smooth migration path as applications grow and evolve. This extends the ability of applications to grow from the relatively simple, to the powerful and complex, yet still selecting a Microchip device.

# PIC24FJ128GB204 FAMILY

---

## 1.2 DMA Controller

PIC24FJ128GB204 family devices also add a Direct Memory Access (DMA) Controller to the existing PIC24F architecture. The DMA acts in concert with the CPU, allowing data to move between data memory and peripherals without the intervention of the CPU, increasing data throughput and decreasing execution time overhead. Six independently programmable channels make it possible to service multiple peripherals at virtually the same time, with each channel peripheral performing a different operation. Many types of data transfer operations are supported.

## 1.3 USB On-The-Go (OTG)

USB On-The-Go provides on-chip functionality as a target device compatible with the USB 2.0 standard, as well as limited stand-alone functionality as a USB embedded host. By implementing USB Host Negotiation Protocol (HNP), the module can also dynamically switch between device and host operation, allowing for a much wider range of versatile USB-enabled applications on a microcontroller platform.

PIC24FJ128GB204 family devices also incorporate an integrated USB transceiver and precision oscillator, minimizing the required complexity of implementing a complete USB device, embedded host, dual role or On-The-Go application.

## 1.4 Cryptographic Engine

The Cryptographic Engine provides a new set of data security options. Using its own free-standing state machines, the engine can independently perform NIST standard encryption and decryption of data, independently of the CPU.

Support for True Random Number Generation (TRNG) and Pseudorandom Number Generation (PRNG); NIST SP800-90 compliant.

## 1.5 Other Special Features

- **Peripheral Pin Select (PPS):** The Peripheral Pin Select feature allows most digital peripherals to be mapped over a fixed set of digital I/O pins. Users may independently map the input and/or output of any one of the many digital peripherals to any one of the I/O pins.
- **Communications:** The PIC24FJ128GB204 family incorporates a range of serial communication peripherals to handle a range of application requirements. There are two independent I<sup>2</sup>C™ modules that support both Master and Slave modes of operation. Devices also have, through the PPS feature, four independent UARTs with built-in IrDA® encoders/decoders, ISO 7816 Smart Card support (UART1 and UART2 only) and three SPI modules with I<sup>2</sup>S and variable data width support.
- **Analog Features:** All members of the PIC24FJ128GB204 family include a 12-bit A/D Converter module and a triple comparator module. The A/D module incorporates a range of new features that allows the converter to assess and make decisions on incoming data, reducing CPU overhead for routine A/D conversions. The comparator module includes three analog comparators that are configurable for a wide range of operations.
- **CTMU Interface:** In addition to their other analog features, members of the PIC24FJ128GB204 family include the CTMU interface module. This provides a convenient method for precision time measurement and pulse generation, and can serve as an interface for capacitive sensors.
- **Enhanced Parallel Master/Parallel Slave Port:** This module allows rapid and transparent access to the microcontroller data bus, and enables the CPU to directly address external data memory. The parallel port can function in Master or Slave mode, accommodating data widths of 4, 8 or 16 bits, and address widths of up to 23 bits in Master modes.
- **Real-Time Clock and Calendar (RTCC):** This module implements a full-featured clock and calendar with alarm functions in hardware, freeing up timer resources and program memory space for use by the core application.
- **Data Signal Modulator (DSM):** The Data Signal Modulator (DSM) allows the user to mix a digital data stream (the “modulator signal”) with a carrier signal to produce a modulated output.

# PIC24FJ128GB204 FAMILY

---

## 1.6 Details on Individual Family Members

Devices in the PIC24FJ128GB204 family are available in 28-pin and 44-pin packages. The general block diagram for all devices is shown in [Figure 1-1](#).

The devices are differentiated from each other in six ways:

1. Flash program memory (64 Kbytes for PIC24FJ64GB2XX devices and 128 Kbytes for PIC24FJ128GB2XX devices).
2. Available I/O pins and ports (21 pins on two ports for 28-pin devices, 35 pins on three ports for 44-pin devices).
3. Available Input Change Notification (ICN) inputs (20 on 28-pin devices and 34 on 44-pin devices).
4. Available remappable pins (14 pins on 28-pin devices and 24 pins on 44-pin devices).
5. Analog input channels for the A/D Converter (12 channels for 44-pin devices and 9 channels for 28-pin devices).

All other features for devices in this family are identical. These are summarized in [Table 1-1](#) and [Table 1-2](#).

A list of the pin features available on the PIC24FJ128GB204 family devices, sorted by function, is shown in [Table 1-3](#). Note that this table shows the pin location of individual peripheral features and not how they are multiplexed on the same pin. This information is provided in the pinout diagrams in the beginning of the data sheet. Multiplexed features are sorted by the priority given to a feature, with the highest priority peripheral being listed first.

**NOTES:**

## 2.0 GUIDELINES FOR GETTING STARTED WITH 16-BIT MICROCONTROLLERS

### 2.1 Basic Connection Requirements

Getting started with the PIC24FJ128GB204 family of 16-bit microcontrollers requires attention to a minimal set of device pin connections before proceeding with development.

The following pins must always be connected:

- All VDD and Vss pins  
(see [Section 2.2 “Power Supply Pins”](#))
- All AVDD and AVss pins, regardless of whether or not the analog device features are used  
(see [Section 2.2 “Power Supply Pins”](#))
- MCLR pin  
(see [Section 2.3 “Master Clear \(MCLR\) Pin”](#))
- ENVREG/DISVREG and VCAP/VDDCORE pins  
(see [Section 2.4 “Voltage Regulator Pins \(ENVREG/DISVREG and VCAP/VDDCORE\)”](#))

These pins must also be connected if they are being used in the end application:

- PGECx/PGEDx pins used for In-Circuit Serial Programming™ (ICSP™) and debugging purposes  
(see [Section 2.5 “ICSP Pins”](#))
- OSCI and OSCO pins when an external oscillator source is used  
(see [Section 2.6 “External Oscillator Pins”](#))

Additionally, the following pins may be required:

- VREF+/VREF- pins used when external voltage reference for analog modules is implemented

**Note:** The AVDD and AVss pins must always be connected, regardless of whether any of the analog modules are being used.

The minimum mandatory connections are shown in [Figure 2-1](#).

**FIGURE 2-1: RECOMMENDED MINIMUM CONNECTIONS**

**Key (all values are recommendations):**

C1 through C6: 0.1  $\mu$ F, 20V ceramic

C7: 10  $\mu$ F, 6.3V or greater, tantalum or ceramic

R1: 10 k $\Omega$

R2: 100 $\Omega$  to 470 $\Omega$

**Note 1:** See [Section 2.4 “Voltage Regulator Pins \(ENVREG/DISVREG and VCAP/VDDCORE\)”](#) for the explanation of the ENVREG/DISVREG pin connections.

**2:** The example shown is for a PIC24F device with five VDD/Vss and AVDD/AVss pairs. Other devices may have more or less pairs; adjust the number of decoupling capacitors appropriately.

# PIC24FJ128GB204 FAMILY

## 2.2 Power Supply Pins

### 2.2.1 DECOUPLING CAPACITORS

The use of decoupling capacitors on every pair of power supply pins, such as VDD, Vss, AVDD and AVss is required.

Consider the following criteria when using decoupling capacitors:

- **Value and type of capacitor:** A  $0.1\ \mu\text{F}$  ( $100\ \text{nF}$ ), 10-20V capacitor is recommended. The capacitor should be a low-ESR device with a resonance frequency in the range of 200 MHz and higher. Ceramic capacitors are recommended.
- **Placement on the printed circuit board:** The decoupling capacitors should be placed as close to the pins as possible. It is recommended to place the capacitors on the same side of the board as the device. If space is constricted, the capacitor can be placed on another layer on the PCB using a via; however, ensure that the trace length from the pin to the capacitor is no greater than 0.25 inch (6 mm).
- **Handling high-frequency noise:** If the board is experiencing high-frequency noise (upward of tens of MHz), add a second ceramic type capacitor in parallel to the above described decoupling capacitor. The value of the second capacitor can be in the range of  $0.01\ \mu\text{F}$  to  $0.001\ \mu\text{F}$ . Place this second capacitor next to each primary decoupling capacitor. In high-speed circuit designs, consider implementing a decade pair of capacitances as close to the power and ground pins as possible (e.g.,  $0.1\ \mu\text{F}$  in parallel with  $0.001\ \mu\text{F}$ ).
- **Maximizing performance:** On the board layout from the power supply circuit, run the power and return traces to the decoupling capacitors first, and then to the device pins. This ensures that the decoupling capacitors are first in the power chain. Equally important is to keep the trace length between the capacitor and the power pins to a minimum, thereby reducing PCB trace inductance.

### 2.2.2 TANK CAPACITORS

On boards with power traces running longer than six inches in length, it is suggested to use a tank capacitor for integrated circuits including microcontrollers to supply a local power source. The value of the tank capacitor should be determined based on the trace resistance that connects the power supply source to the device, and the maximum current drawn by the device in the application. In other words, select the tank capacitor so that it meets the acceptable voltage sag at the device. Typical values range from  $4.7\ \mu\text{F}$  to  $47\ \mu\text{F}$ .

## 2.3 Master Clear (MCLR) Pin

The MCLR pin provides two specific device functions: device Reset, and device programming and debugging. If programming and debugging are not required in the end application, a direct connection to VDD may be all that is required. The addition of other components, to help increase the application's resistance to spurious Resets from voltage sags, may be beneficial. A typical configuration is shown in [Figure 2-1](#). Other circuit designs may be implemented, depending on the application's requirements.

During programming and debugging, the resistance and capacitance that can be added to the pin must be considered. Device programmers and debuggers drive the MCLR pin. Consequently, specific voltage levels ( $\text{VIH}$  and  $\text{VIL}$ ) and fast signal transitions must not be adversely affected. Therefore, specific values of  $R1$  and  $C1$  will need to be adjusted based on the application and PCB requirements. For example, it is recommended that the capacitor,  $C1$ , be isolated from the MCLR pin during programming and debugging operations by using a jumper ([Figure 2-2](#)). The jumper is replaced for normal run-time operations.

Any components associated with the MCLR pin should be placed within 0.25 inch (6 mm) of the pin.

**FIGURE 2-2: EXAMPLE OF MCLR PIN CONNECTIONS**

## 2.4 Voltage Regulator Pins (ENVREG/DISVREG and VCAP/VDDCORE)

**Note:** This section applies only to PIC24FJ devices with an on-chip voltage regulator.

The on-chip voltage regulator enable/disable pin (ENVREG or DISVREG, depending on the device family) must always be connected directly to either a supply voltage or to ground. The particular connection is determined by whether or not the regulator is to be used:

- For ENVREG, tie to VDD to enable the regulator, or to ground to disable the regulator
- For DISVREG, tie to ground to enable the regulator or to VDD to disable the regulator

Refer to [Section 30.2 “On-Chip Voltage Regulator”](#) for details on connecting and using the on-chip regulator.

When the regulator is enabled, a low-ESR ( $< 5\Omega$ ) capacitor is required on the VCAP/VDDCORE pin to stabilize the voltage regulator output voltage. The VCAP/VDDCORE pin must not be connected to VDD and must use a capacitor of  $10 \mu F$  connected to ground. The type can be ceramic or tantalum. Suitable examples of capacitors are shown in [Table 2-1](#). Capacitors with equivalent specification can be used.

Designers may use [Figure 2-3](#) to evaluate ESR equivalence of candidate devices.

The placement of this capacitor should be close to VCAP/VDDCORE. It is recommended that the trace length not exceed 0.25 inch (6 mm). Refer to [Section 33.0 “Electrical Characteristics”](#) for additional information.

When the regulator is disabled, the VCAP/VDDCORE pin must be tied to a voltage supply at the VDDCORE level. Refer to [Section 33.0 “Electrical Characteristics”](#) for information on VDD and VDDCORE.

**FIGURE 2-3: FREQUENCY vs. ESR PERFORMANCE FOR SUGGESTED VCAP**

**Note:** Typical data measurement at  $+25^\circ C$ , 0V DC bias.

**TABLE 2-1: SUITABLE CAPACITOR EQUIVALENTS**

# PIC24FJ128GB204 FAMILY

## 2.4.1 CONSIDERATIONS FOR CERAMIC CAPACITORS

In recent years, large value, low-voltage, surface-mount ceramic capacitors have become very cost effective in sizes up to a few tens of microfarad. The low-ESR, small physical size and other properties make ceramic capacitors very attractive in many types of applications.

Ceramic capacitors are suitable for use with the internal voltage regulator of this microcontroller. However, some care is needed in selecting the capacitor to ensure that it maintains sufficient capacitance over the intended operating range of the application.

Typical low-cost, 10  $\mu\text{F}$  ceramic capacitors are available in X5R, X7R and Y5V dielectric ratings (other types are also available, but are less common). The initial tolerance specifications for these types of capacitors are often specified as  $\pm 10\%$  to  $\pm 20\%$  (X5R and X7R), or  $-20\%/+80\%$  (Y5V). However, the effective capacitance that these capacitors provide in an application circuit will also vary based on additional factors, such as the applied DC bias voltage and the temperature. The total in-circuit tolerance is, therefore, much wider than the initial tolerance specification.

The X5R and X7R capacitors typically exhibit satisfactory temperature stability (ex:  $\pm 15\%$  over a wide temperature range, but consult the manufacturer's data sheets for exact specifications). However, Y5V capacitors typically have extreme temperature tolerance specifications of  $+22\%/-82\%$ . Due to the extreme temperature tolerance, a 10  $\mu\text{F}$  nominal rated Y5V type capacitor may not deliver enough total capacitance to meet minimum internal voltage regulator stability and transient response requirements. Therefore, Y5V capacitors are not recommended for use with the internal regulator if the application must operate over a wide temperature range.

In addition to temperature tolerance, the effective capacitance of large value ceramic capacitors can vary substantially, based on the amount of DC voltage applied to the capacitor. This effect can be very significant, but is often overlooked or is not always documented.

Typical DC bias voltage vs. capacitance graph for X7R type capacitors is shown in [Figure 2-4](#).

**FIGURE 2-4: DC BIAS VOLTAGE vs. CAPACITANCE CHARACTERISTICS**

When selecting a ceramic capacitor to be used with the internal voltage regulator, it is suggested to select a high-voltage rating, so that the operating voltage is a small percentage of the maximum rated capacitor voltage. For example, choose a ceramic capacitor rated at 16V for the 2.5V or 1.8V core voltage. Suggested capacitors are shown in [Table 2-1](#).

## 2.5 ICSP Pins

The PGECx and PGEDx pins are used for In-Circuit Serial Programming (ICSP) and debugging purposes. It is recommended to keep the trace length between the ICSP connector and the ICSP pins on the device as short as possible. If the ICSP connector is expected to experience an ESD event, a series resistor is recommended, with the value in the range of a few tens of ohms, not to exceed 100 $\Omega$ .

Pull-up resistors, series diodes and capacitors on the PGECx and PGEDx pins are not recommended as they will interfere with the programmer/debugger communications to the device. If such discrete components are an application requirement, they should be removed from the circuit during programming and debugging. Alternatively, refer to the AC/DC characteristics and timing requirements information in the respective device Flash programming specification for information on capacitive loading limits and pin input voltage high (VIH) and input low (VIL) requirements.

For device emulation, ensure that the "Communication Channel Select" (i.e., PGECx/PGEDx pins), programmed into the device, matches the physical connections for the ICSP to the Microchip debugger/emulator tool.

For more information on available Microchip development tools connection requirements, refer to [Section 31.0 "Development Support"](#).

## 2.6 External Oscillator Pins

Many microcontrollers have options for at least two oscillators: a high-frequency Primary Oscillator and a low-frequency Secondary Oscillator (refer to [Section 9.0 “Oscillator Configuration”](#) for details).

The oscillator circuit should be placed on the same side of the board as the device. Place the oscillator circuit close to the respective oscillator pins with no more than 0.5 inch (12 mm) between the circuit components and the pins. The load capacitors should be placed next to the oscillator itself, on the same side of the board.

Use a grounded copper pour around the oscillator circuit to isolate it from surrounding circuits. The grounded copper pour should be routed directly to the MCU ground. Do not run any signal traces or power traces inside the ground pour. Also, if using a two-sided board, avoid any traces on the other side of the board where the crystal is placed.

Layout suggestions are shown in [Figure 2-5](#). In-line packages may be handled with a single-sided layout that completely encompasses the oscillator pins. With fine-pitch packages, it is not always possible to completely surround the pins and components. A suitable solution is to tie the broken guard sections to a mirrored ground layer. In all cases, the guard trace(s) must be returned to ground.

In planning the application’s routing and I/O assignments, ensure that adjacent port pins, and other signals in close proximity to the oscillator, are benign (i.e., free of high frequencies, short rise and fall times and other similar noise).

For additional information and design guidance on oscillator circuits, please refer to these Microchip Application Notes, available at the corporate web site ([www.microchip.com](http://www.microchip.com)):

---

## 2.7 Configuration of Analog and Digital Pins During ICSP Operations

If an ICSP compliant emulator is selected as a debugger, it automatically initializes all of the A/D input pins (ANx) as “digital” pins. Depending on the particular device, this is done by setting all bits in the ADxPCFG register(s) or clearing all bits in the ANSx registers.

All PIC24F devices will have either one or more ADxPCFG registers, or several ANSx registers (one for each port); no device will have both. Refer to [Section 11.2 “Configuring Analog Port Pins \(ANSx\)”](#) for more specific information.

The bits in these registers that correspond to the A/D pins that initialized the emulator must not be changed by the user application firmware; otherwise, communication errors will result between the debugger and the device.

If your application needs to use certain A/D pins as analog input pins during the debug session, the user application must modify the appropriate bits during initialization of the A/D module, as follows:

- For devices with an ADxPCFG register, clear the bits corresponding to the pin(s) to be configured as analog. Do not change any other bits, particularly those corresponding to the PGECx/PGEDx pair, at any time.
- For devices with ANSx registers, set the bits corresponding to the pin(s) to be configured as analog. Do not change any other bits, particularly those corresponding to the PGECx/PGEDx pair, at any time.

When a Microchip debugger/emulator is used as a programmer, the user application firmware must correctly configure the ADxPCFG or ANSx registers. Automatic initialization of this register is only done during debugger operation. Failure to correctly configure the register(s) will result in all A/D pins being recognized as analog input pins, resulting in the port value being read as a logic ‘0’, which may affect user application functionality.

## 2.8 Unused I/Os

Unused I/O pins should be configured as outputs and driven to a logic low state. Alternatively, connect a 1 k $\Omega$  to 10 k $\Omega$  resistor to Vss on unused pins and drive the output to logic low.

## 3.0 CPU

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information on the CPU, refer to the “*dsPIC33/PIC24 Family Reference Manual*”, “**CPU with Extended Data Space (EDS)**” (DS39732). The information in this data sheet supersedes the information in the FRM.

The PIC24F CPU has a 16-bit (data) modified Harvard architecture with an enhanced instruction set and a 24-bit instruction word with a variable length opcode field. The Program Counter (PC) is 23 bits wide and addresses up to 4M instructions of user program memory space. A single-cycle instruction prefetch mechanism is used to help maintain throughput and provides predictable execution. All instructions execute in a single cycle, with the exception of instructions that change the program flow, the double-word move (MOV.D) instruction and the table instructions. Overhead-free program loop constructs are supported using the REPEAT instructions, which are interruptible at any point.

PIC24F devices have sixteen, 16-bit Working registers in the programmer's model. Each of the Working registers can act as a Data, Address or Address Offset register. The 16<sup>th</sup> Working register (W15) operates as a Software Stack Pointer (SSP) for interrupts and calls.

The lower 32 Kbytes of the Data Space (DS) can be accessed linearly. The upper 32 Kbytes of the Data Space are referred to as Extended Data Space to which the extended data RAM, EPMP memory space or program memory can be mapped.

The Instruction Set Architecture (ISA) has been significantly enhanced beyond that of the PIC18, but maintains an acceptable level of backward compatibility. All PIC18 instructions and addressing modes are supported, either directly, or through simple macros. Many of the ISA enhancements have been driven by compiler efficiency needs.

The core supports Inherent (no operand), Relative, Literal and Memory Direct Addressing modes, along with three groups of addressing modes. All modes support Register Direct and various Register Indirect modes. Each group offers up to seven addressing modes. Instructions are associated with predefined addressing modes depending upon their functional requirements.

For most instructions, the core is capable of executing a data (or program data) memory read, a Working register (data) read, a data memory write and a program (instruction) memory read per instruction cycle. As a result, three parameter instructions can be supported, allowing trinary operations (that is, A + B = C) to be executed in a single cycle.

A high-speed, 17-bit x 17-bit multiplier has been included to significantly enhance the core arithmetic capability and throughput. The multiplier supports Signed, Unsigned and Mixed mode, 16-bit x 16-bit or 8-bit x 8-bit, integer multiplication. All multiply instructions execute in a single cycle.

The 16-bit ALU has been enhanced with integer divide assist hardware that supports an iterative non-restoring divide algorithm. It operates in conjunction with the REPEAT instruction looping mechanism and a selection of iterative divide instructions to support 32-bit (or 16-bit), divided by 16-bit, integer signed and unsigned division. All divide operations require 19 cycles to complete but are interruptible at any cycle boundary.

The PIC24F has a vectored exception scheme with up to 8 sources of non-maskable traps and up to 118 interrupt sources. Each interrupt source can be assigned to one of seven priority levels.

A block diagram of the CPU is shown in [Figure 3-1](#).

### 3.1 Programmer's Model

The programmer's model for the PIC24F is shown in [Figure 3-2](#). All registers in the programmer's model are memory-mapped and can be manipulated directly by instructions.

A description of each register is provided in [Table 3-1](#). All registers associated with the programmer's model are memory-mapped.

bit 7							bit 0

#### Legend:

R = Readable bit

W = Writable bit

U = Unimplemented bit, read as '0'

-n = Value at POR

'1' = Bit is set

'0' = Bit is cleared

x = Bit is unknown

- bit 15-9      **Unimplemented:** Read as '0'
- bit 8      **DC:** ALU Half Carry/Borrow bit  
1 = A carry out from the 4<sup>th</sup> low-order bit (for byte-sized data) or 8<sup>th</sup> low-order bit (for word-sized data) of the result occurred  
0 = No carry out from the 4<sup>th</sup> or 8<sup>th</sup> low-order bit of the result has occurred
- bit 7-5      **IPL<2:0>:** CPU Interrupt Priority Level Status bits<sup>(1,2)</sup>  
111 = CPU Interrupt Priority Level is 7 (15); user interrupts are disabled  
110 = CPU Interrupt Priority Level is 6 (14)  
101 = CPU Interrupt Priority Level is 5 (13)  
100 = CPU Interrupt Priority Level is 4 (12)  
011 = CPU Interrupt Priority Level is 3 (11)  
010 = CPU Interrupt Priority Level is 2 (10)  
001 = CPU Interrupt Priority Level is 1 (9)  
000 = CPU Interrupt Priority Level is 0 (8)
- bit 4      **RA:** REPEAT Loop Active bit  
1 = REPEAT loop is in progress  
0 = REPEAT loop is not in progress
- bit 3      **N:** ALU Negative bit  
1 = Result was negative  
0 = Result was not negative (zero or positive)
- bit 2      **OV:** ALU Overflow bit  
1 = Overflow occurred for signed (2's complement) arithmetic in this arithmetic operation  
0 = No overflow has occurred
- bit 1      **Z:** ALU Zero bit  
1 = An operation, which affects the Z bit, has set it at some time in the past  
0 = The most recent operation, which affects the Z bit, has cleared it (i.e., a non-zero result)
- bit 0      **C:** ALU Carry/Borrow bit  
1 = A carry out from the Most Significant bit (MSb) of the result occurred  
0 = No carry out from the Most Significant bit of the result occurred

**Note 1:** The IPLx Status bits are read-only when NSTDIS (INTCON1<15>) = 1.

**2:** The IPLx Status bits are concatenated with the IPL3 Status (CORCON<3>) bit to form the CPU Interrupt Priority Level (IPL). The value in parentheses indicates the IPL when IPL3 = 1.

  0 = CPU Interrupt Priority Level is 7 or less

bit 2      **Reserved:** Read as '1'

bit 1-0      **Unimplemented:** Read as '0'

**Note 1:** The IPL3 bit is concatenated with the IPL<2:0> bits (SR<7:5>) to form the CPU Interrupt Priority Level; see [Register 3-1](#) for bit description.

# PIC24FJ128GB204 FAMILY

---

### 3.3 Arithmetic Logic Unit (ALU)

The PIC24F ALU is 16 bits wide and is capable of addition, subtraction, bit shifts and logic operations. Unless otherwise mentioned, arithmetic operations are 2's complement in nature. Depending on the operation, the ALU may affect the values of the Carry (C), Zero (Z), Negative (N), Overflow (OV) and Digit Carry (DC) Status bits in the SR register. The C and DC Status bits operate as Borrow and Digit Borrow bits, respectively, for subtraction operations.

The ALU can perform 8-bit or 16-bit operations, depending on the mode of the instruction that is used. Data for the ALU operation can come from the W register array, or data memory, depending on the addressing mode of the instruction. Likewise, output data from the ALU can be written to the W register array or a data memory location.

The PIC24F CPU incorporates hardware support for both multiplication and division. This includes a dedicated hardware multiplier and support hardware for 16-bit divisor division.

#### 3.3.1 MULTIPLIER

The ALU contains a high-speed, 17-bit x 17-bit multiplier. It supports unsigned, signed or mixed sign operation in several multiplication modes:

- 16-bit x 16-bit signed
- 16-bit x 16-bit unsigned
- 16-bit signed x 5-bit (literal) unsigned
- 16-bit unsigned x 16-bit unsigned
- 16-bit unsigned x 5-bit (literal) unsigned
- 16-bit unsigned x 16-bit signed
- 8-bit unsigned x 8-bit unsigned

#### 3.3.2 DIVIDER

The divide block supports 32-bit/16-bit and 16-bit/16-bit signed and unsigned integer divide operations with the following data sizes:

1. 32-bit signed/16-bit signed divide
2. 32-bit unsigned/16-bit unsigned divide
3. 16-bit signed/16-bit signed divide
4. 16-bit unsigned/16-bit unsigned divide

The quotient for all divide instructions ends up in W0 and the remainder in W1. The 16-bit signed and unsigned DIV instructions can specify any W register for both the 16-bit divisor (Wn), and any W register (aligned) pair (W(m + 1):Wm) for the 32-bit dividend. The divide algorithm takes one cycle per bit of divisor, so both 32-bit/16-bit and 16-bit/16-bit instructions take the same number of cycles to execute.

#### 3.3.3 MULTI-BIT SHIFT SUPPORT

The PIC24F ALU supports both single bit and single-cycle, multi-bit arithmetic and logic shifts. Multi-bit shifts are implemented using a shifter block, capable of performing up to a 15-bit arithmetic right shift, or up to a 15-bit left shift, in a single cycle. All multi-bit shift instructions only support Register Direct Addressing for both the operand source and result destination.

A full summary of instructions that use the shift operation is provided in [Table 3-2](#).

**TABLE 3-2: INSTRUCTIONS THAT USE THE SINGLE BIT AND MULTI-BIT SHIFT OPERATION**

Instruction	Description
ASR	Arithmetic Shift Right Source register by one or more bits.
SL	Shift Left Source register by one or more bits.
LSR	Logical Shift Right Source register by one or more bits.

## 4.0 MEMORY ORGANIZATION

As Harvard architecture devices, PIC24F microcontrollers feature separate program and data memory spaces and buses. This architecture also allows direct access of program memory from the Data Space (DS) during code execution.

### 4.1 Program Memory Space

The program address memory space of the PIC24FJ128GB204 family devices is 4M instructions. The space is addressable by a 24-bit value derived

from either the 23-bit Program Counter (PC) during program execution, or from table operation or Data Space remapping, as described in [Section 4.3 “Interfacing Program and Data Memory Spaces”](#).

User access to the program memory space is restricted to the lower half of the address range (000000h to 7FFFFFFh). The exception is the use of TBLRD/TBLWT operations, which use TBLPAG<7> to permit access to the Configuration bits and Device ID sections of the configuration memory space.

Memory maps for the PIC24FJ128GB204 family of devices are shown in [Figure 4-1](#).

**FIGURE 4-1: PROGRAM SPACE MEMORY MAP FOR PIC24FJ128GB204 FAMILY DEVICES**

# PIC24FJ128GB204 FAMILY

## 4.1.1 PROGRAM MEMORY ORGANIZATION

The program memory space is organized in word-addressable blocks. Although it is treated as 24 bits wide, it is more appropriate to think of each address of the program memory as a lower and upper word, with the upper byte of the upper word being unimplemented. The lower word always has an even address, while the upper word has an odd address ([Figure 4-2](#)).

Program memory addresses are always word-aligned on the lower word and addresses are incremented or decremented by two during code execution. This arrangement also provides compatibility with data memory space addressing and makes it possible to access data in the program memory space.

## 4.1.2 HARD MEMORY VECTORS

All PIC24F devices reserve the addresses between 000000h and 000200h for hard-coded program execution vectors. A hardware Reset vector is provided to redirect code execution from the default value of the PC on device Reset to the actual start of code. A GOTO instruction is programmed by the user at 000000h with the actual address for the start of code at 000002h.

PIC24F devices also have two Interrupt Vector Tables (IVTs), located from 000004h to 0000FFh and 000100h to 0001FFh. These vector tables allow each of the many device interrupt sources to be handled by separate ISRs. A more detailed discussion of the Interrupt Vector Tables is provided in [Section 8.1 “Interrupt Vector Table”](#).

**FIGURE 4-2: PROGRAM MEMORY ORGANIZATION**

## 4.1.3 FLASH CONFIGURATION WORDS

In PIC24FJ128GB204 family devices, the top four words of on-chip program memory are reserved for configuration information. On device Reset, the configuration information is copied into the appropriate Configuration register. The addresses of the Flash Configuration Word for devices in the PIC24FJ128GB204 family are shown in [Table 4-1](#). Their location in the memory map is shown with the other memory vectors in [Figure 4-1](#).

The Configuration Words in program memory are a compact format. The actual Configuration bits are mapped in several different registers in the configuration memory space. Their order in the Flash Configuration Words does not reflect a corresponding arrangement in the configuration space. Additional details on the device Configuration Words are provided in [Section 30.0 “Special Features”](#).

**TABLE 4-1: FLASH CONFIGURATION WORDS FOR PIC24FJ128GB204 FAMILY DEVICES**

Device	Program Memory (Words)	Configuration Word Addresses
PIC24FJ64GB2XX	22,016	00ABF8h:00ABFEh
PIC24FJ128GB2XX	44,032	0157F8h:0157FEh

## 4.2 Data Memory Space

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Data Memory with Extended Data Space (EDS)” (DS39733). The information in this data sheet supersedes the information in the FRM.

The PIC24F core has a 16-bit wide data memory space, addressable as a single linear range. The Data Space (DS) is accessed using two Address Generation Units (AGUs), one each for read and write operations. The Data Space memory map is shown in [Figure 4-3](#).

The 16-bit wide data addresses in the data memory space point to bytes within the Data Space. This gives a DS address range of 64 Kbytes or 32K words. The lower half (0000h to 7FFFh) is used for implemented (on-chip) memory addresses.

The upper half of data memory address space (8000h to FFFFh) is used as a window into the Extended Data Space (EDS). This allows the microcontroller to directly access a greater range of data beyond the standard 16-bit address range. EDS is discussed in detail in [Section 4.2.5 “Extended Data Space \(EDS\)”](#).

The lower half of DS is compatible with previous PIC24F microcontrollers without EDS. All PIC24FJ128GB204 family devices implement 8 Kbytes of data RAM in the lower half of DS, from 0800h to 27FFh.

### 4.2.1 DATA SPACE WIDTH

The data memory space is organized in byte-addressable, 16-bit wide blocks. Data is aligned in data memory and registers as 16-bit words, but all Data Space Effective Addresses (EAs) resolve to bytes. The Least Significant Bytes (LSBs) of each word have even addresses, while the Most Significant Bytes (MSBs) have odd addresses.

**FIGURE 4-3: DATA SPACE MEMORY MAP FOR PIC24FJ128GB204 FAMILY DEVICES**

# PIC24FJ128GB204 FAMILY

## 4.2.2 DATA MEMORY ORGANIZATION AND ALIGNMENT

To maintain backward compatibility with PIC® MCUs and improve Data Space memory usage efficiency, the PIC24F instruction set supports both word and byte operations. As a consequence of byte accessibility, all Effective Address (EA) calculations are internally scaled to step through word-aligned memory. For example, the core recognizes that Post-Modified Register Indirect Addressing mode [Ws++] will result in a value of Ws + 1 for byte operations and Ws + 2 for word operations.

Data byte reads will read the complete word, which contains the byte, using the LSB of any EA to determine which byte to select. The selected byte is placed onto the LSB of the data path. That is, data memory and registers are organized as two parallel, byte-wide entities with shared (word) address decode but separate write lines. Data byte writes only write to the corresponding side of the array or register which matches the byte address.

All word accesses must be aligned to an even address. Misaligned word data fetches are not supported, so care must be taken when mixing byte and word operations or translating from 8-bit MCU code. If a misaligned read or write is attempted, an address error trap will be generated. If the error occurred on a read, the instruction underway is completed; if it occurred on a write, the instruction will be executed but the write will not occur. In either case, a trap is then executed, allowing the system and/or user to examine the machine state prior to execution of the address Fault.

All byte loads into any W register are loaded into the LSB. The Most Significant Byte (MSB) is not modified.

A Sign-Extend (SE) instruction is provided to allow users to translate 8-bit signed data to 16-bit signed values. Alternatively, for 16-bit unsigned data, users can clear the MSB of any W register by executing a Zero-Extend (ZE) instruction on the appropriate address.

Although most instructions are capable of operating on word or byte data sizes, it should be noted that some instructions operate only on words.

## 4.2.3 NEAR DATA SPACE

The 8-Kbyte area, between 0000h and 1FFFh, is referred to as the Near Data Space. Locations in this space are directly addressable via a 13-bit absolute address field within all memory direct instructions. The remainder of the Data Space is addressable indirectly. Additionally, the whole Data Space is addressable using MOV instructions, which support Memory Direct Addressing with a 16-bit address field.

## 4.2.4 SPECIAL FUNCTION REGISTER (SFR) SPACE

The first 2 Kbytes of the Near Data Space, from 0000h to 07FFh, are primarily occupied with Special Function Registers (SFRs). These are used by the PIC24F core and peripheral modules for controlling the operation of the device.

SFRs are distributed among the modules that they control and are generally grouped together by the module. Much of the SFR space contains unused addresses; these are read as '0'. A diagram of the SFR space, showing where the SFRs are actually implemented, is shown in [Table 4-2](#). Each implemented area indicates a 32-byte region where at least one address is implemented as an SFR. A complete list of implemented SFRs, including their addresses, is shown in [Table 4-3](#) through [Table 4-33](#).

TABLE 4-2: IMPLEMENTED REGIONS OF SFR DATA SPACE

SFR Space Address

## 4.2.5 EXTENDED DATA SPACE (EDS)

The Extended Data Space (EDS) allows PIC24F devices to address a much larger range of data than would otherwise be possible with a 16-bit address range. EDS includes any additional internal data memory not directly accessible by the lower 32-Kbyte data address space and any external memory through the Enhanced Parallel Master Port (EPMP).

In addition, EDS also allows read access to the program memory space. This feature is called Program Space Visibility (PSV) and is discussed in detail in [Section 4.3.3 “Reading Data from Program Memory Using EDS”](#).

[Figure 4-4](#) displays the entire EDS space. The EDS is organized as pages, called EDS pages, with one page equal to the size of the EDS window (32 Kbytes). A particular EDS page is selected through the Data Space Read register (DSRPAG) or Data Space Write register (DSWPAG). For PSV, only the DSRPAG register is used. The combination of the DSRPAG register value and the 16-bit wide data address forms a 24-bit Effective Address (EA).

The data addressing range of PIC24FJ128GB204 family devices depends on the version of the Enhanced Parallel Master Port implemented on a particular device; this is, in turn, a function of device pin count. [Table 4-34](#) lists the total memory accessible by each of the devices in this family. For more details on accessing external memory using EPMP, refer to the “*dsPIC33/PIC24 Family Reference Manual*”, “**Enhanced Parallel Master Port (EPMP)**” (DS39730).

**TABLE 4-34: TOTAL ACCESSIBLE DATA MEMORY**

Family	Internal RAM	External RAM Access Using EPMP
PIC24FJXXXGB204	8K	Up to 16 Mbytes
PIC24FJXXXGB202	8K	Up to 64K

**Note:** Accessing Page 0 in the EDS window will generate an address error trap as Page 0 is the base data memory (data locations, 0800h to 7FFFh, in the lower Data Space).

**FIGURE 4-4: EXTENDED DATA SPACE (EDS)**

# PIC24FJ128GB204 FAMILY

## 4.2.5.1 Data Read from EDS

In order to read the data from the EDS space first, an Address Pointer is set up by loading the required EDS page number into the DSRPAG register and assigning the offset address to one of the W registers. Once the above assignment is done, the EDS window is enabled by setting bit 15 of the Working register assigned with the offset address; then, the contents of the pointed EDS location can be read.

Figure 4-5 illustrates how the EDS space address is generated for read operations.

When the Most Significant bit of the EA is ‘1’ and DSRPAG<9> = 0, the lower 9 bits of DSRPAG are concatenated to the lower 15 bits of the EA to form a 24-bit EDS space address for read operations.

Example 4-1 shows how to read a byte, word and double-word from EDS.

**Note:** All read operations from EDS space have an overhead of one instruction cycle. Therefore, a minimum of two instruction cycles is required to complete an EDS read. EDS reads under the REPEAT instruction; the first two accesses take three cycles and the subsequent accesses take one cycle.

**FIGURE 4-5: EDS ADDRESS GENERATION FOR READ OPERATIONS**

## EXAMPLE 4-1: EDS READ CODE IN ASSEMBLY

```
; Set the EDS page from where the data to be read
    mov      #0x0002, w0
    mov      w0, DSRPAG      ;page 2 is selected for read
    mov      #0x0800, w1      ;select the location (0x800) to be read
    bset    w1, #15          ;set the MSB of the base address, enable EDS mode

;Read a byte from the selected location
    mov.b   [w1++], w2      ;read Low byte
    mov.b   [w1++], w3      ;read High byte

;Read a word from the selected location
    mov     [w1], w2          ;

;Read Double - word from the selected location
    mov.d   [w1], w2          ;two word read, stored in w2 and w3
```

## 4.2.5.2 Data Write into EDS

In order to write data to EDS space, such as in EDS reads, an Address Pointer is set up by loading the required EDS page number into the DSWPAG register and assigning the offset address to one of the W registers. Once the above assignment is done, then the EDS window is enabled by setting bit 15 of the Working register, assigned with the offset address, and the accessed location can be written.

**Figure 4-2** illustrates how the EDS space address is generated for write operations.

When the MSBs of EA are '1', the lower 9 bits of DSWPAG are concatenated to the lower 15 bits of the EA to form a 24-bit EDS address for write operations. **Example 4-2** shows how to write a byte, word and double-word to EDS.

The Data Space Page registers (DSRPAG/DSWPAG) do not update automatically while crossing a page boundary when the rollover happens from 0xFFFF to

0x8000. While developing code in assembly, care must be taken to update the Data Space Page registers when an Address Pointer crosses the page boundary. The 'C' compiler keeps track of the addressing, and increments or decrements the Page registers accordingly, while accessing contiguous data memory locations.

**Note 1:** All write operations to EDS are executed in a single cycle.

- 2: Use of Read-Modify-Write operation on any EDS location under a REPEAT instruction is not supported. For example, BCLR, BSW, BTG, RLC f, RLNC f, RRC f, RRNC f, ADD f, SUB f, SUBR f, AND f, IOR f, XOR f, ASR f, ASL f.
- 3: Use the DSRPAG register while performing Read-Modify-Write operations.

**FIGURE 4-6: EDS ADDRESS GENERATION FOR WRITE OPERATIONS**

## EXAMPLE 4-2: EDS WRITE CODE IN ASSEMBLY

```

; Set the EDS page where the data to be written
    mov     #0x0002, w0
    mov     w0, DSWPAG      ;page 2 is selected for write
    mov     #0x800,  w1      ;select the location (0x800) to be written
    bset   w1, #15          ;set the MSB of the base address, enable EDS mode

;Write a byte to the selected location
    mov     #0x00A5, w2
    mov     #0x003C, w3
    mov.b   w2, [w1++]        ;write Low byte
    mov.b   w3, [w1++]        ;write High byte

;Write a word to the selected location
    mov     #0x1234, w2      ;
    mov     w2, [w1]           ;

;Write a Double - word to the selected location
    mov     #0x1122, w2
    mov     #0x4455, w3
    mov.d   w2, [w1]          ;2 EDS writes

```

# PIC24FJ128GB204 FAMILY

TABLE 4-35: EDS MEMORY ADDRESS WITH DIFFERENT PAGES AND ADDRESSES

DSRPAG (Data Space Read Register)	DSWPAG (Data Space Write Register)	Source/Destination Address while Indirect Addressing	24-Bit EA Pointing to EDS	Comment
x <sup>(1)</sup>	x <sup>(1)</sup>	0000h to 1FFFh	000000h to 001FFFh	Near Data Space <sup>(2)</sup>
		2000h to 7FFFh	002000h to 007FFFh	
001h	001h	8000h to FFFFh	008000h to 00FFFEh	EPMP Memory Space
002h	002h		010000h to 017FFEh	
003h	003h		018000h to 0187FEh	
.	.		.	
.	.		.	
.	.		.	
.	.		.	
1FFh	1FFh		FF8000h to FFFFFFFh	
000h	000h		Invalid Address	Address Error Trap <sup>(3)</sup>

**Note 1:** If the source/destination address is below 8000h, the DSRPAG and DSWPAG registers are not considered.

**2:** This Data Space can also be accessed by Direct Addressing.

**3:** When the source/destination address is above 8000h and DSRPAG/DSWPAG are '0', an address error trap will occur.

## 4.2.6 SOFTWARE STACK

Apart from its use as a Working register, the W15 register in PIC24F devices is also used as a Software Stack Pointer (SSP). The pointer always points to the first available free word and grows from lower to higher addresses. It decrements for stack pops and post-increments for stack pushes, as shown in **Figure 4-7**. Note that for a PC push during any CALL instruction, the MSB of the PC is zero-extended before the push, ensuring that the MSB is always clear.

**Note:** A PC push during exception processing will concatenate the SRL Register to the MSB of the PC prior to the push.

The Stack Pointer Limit Value (SPLIM) register, associated with the Stack Pointer, sets an upper address boundary for the stack. SPLIM is uninitialized at Reset. As is the case for the Stack Pointer, SPLIM<0> is forced to '0' as all stack operations must be word-aligned. Whenever an EA is generated using W15 as a Source or Destination Pointer, the resulting address is compared with the value in SPLIM. If the contents of the Stack Pointer (W15) and the SPLIM register are equal, and a push operation is performed, a stack error trap will not occur. The stack error trap will occur on a subsequent push operation. Thus, for

example, if it is desirable to cause a stack error trap when the stack grows beyond address, 2000h in RAM, initialize the SPLIM with the value, 1FFEh.

Similarly, a Stack Pointer underflow (stack error) trap is generated when the Stack Pointer address is found to be less than 0800h. This prevents the stack from interfering with the SFR space.

A write to the SPLIM register should not be immediately followed by an indirect read operation using W15.

**FIGURE 4-7: CALL STACK FRAME**

## 4.3 Interfacing Program and Data Memory Spaces

The PIC24F architecture uses a 24-bit wide program space and 16-bit wide Data Space. The architecture is also a modified Harvard scheme, meaning that data can also be present in the program space. To use this data successfully, it must be accessed in a way that preserves the alignment of information in both spaces. Aside from normal execution, the PIC24F architecture provides two methods by which program space can be accessed during operation:

- Using table instructions to access individual bytes or words anywhere in the program space
- Remapping a portion of the program space into the Data Space (Program Space Visibility)

Table instructions allow an application to read or write to small areas of the program memory. This makes the method ideal for accessing data tables that need to be updated from time to time. It also allows access to all bytes of the program word. The remapping method allows an application to access a large block of data on a read-only basis, which is ideal for look-ups from a large table of static data. It can only access the least significant word of the program word.

### 4.3.1 ADDRESSING PROGRAM SPACE

Since the address ranges for the data and program spaces are 16 and 24 bits, respectively, a method is needed to create a 23-bit or 24-bit program address from 16-bit data registers. The solution depends on the interface method to be used.

For table operations, the 8-bit Table Memory Page Address register (TBLPAG) is used to define a 32K word region within the program space. This is concatenated with a 16-bit EA to arrive at a full 24-bit program space address. In this format, the MSbs of TBLPAG are used to determine if the operation occurs in the user memory ( $TBLPAG<7> = 0$ ) or the configuration memory ( $TBLPAG<7> = 1$ ).

For remapping operations, the 10-bit Extended Data Space Read register (DSRPAG) is used to define a 16K word page in the program space. When the Most Significant bit (MSb) of the EA is '1', and the MSb (bit 9) of DSRPAG is '1', the lower 8 bits of DSRPAG are concatenated with the lower 15 bits of the EA to form a 23-bit program space address. The DSRPAG<8> bit decides whether the lower word (when the bit is '0') or the higher word (when the bit is '1') of program memory is mapped. Unlike table operations, this strictly limits remapping operations to the user memory area.

**Table 4-36** and **Figure 4-8** show how the program EA is created for table operations and remapping accesses from the data EA. Here, P<23:0> refer to a program space word, whereas D<15:0> refer to a Data Space word.

**TABLE 4-36: PROGRAM SPACE ADDRESS CONSTRUCTION**

Access Type	Access Space	Program Space Address						
		<23>	<22:16>	<15>	<14:1>	<0>		
Instruction Access (Code Execution)	User	0	PC<22:1>			0		
		0xx xxxx xxxx xxxx xxxx xxxx0						
TBLRD/TBLWT (Byte/Word Read/Write)	User	TBLPAG<7:0>		Data EA<15:0>				
		0xxx xxxx		xxxx xxxx xxxx xxxx				
	Configuration	TBLPAG<7:0>		Data EA<15:0>				
		1xxx xxxx		xxxx xxxx xxxx xxxx				
Program Space Visibility (Block Remap/Read)	User	0	DSRPAG<7:0> <sup>(2)</sup>		Data EA<14:0> <sup>(1)</sup>			
		0	xxxx xxxx		xxx xxxx xxxx xxxx			

**Note 1:** Data EA<15> is always '1' in this case, but is not used in calculating the program space address. Bit 15 of the address is DSRPAG<0>.

**2:** DSRPAG<9> is always '1' in this case. DSRPAG<8> decides whether the lower word or higher word of program memory is read. When DSRPAG<8> is '0', the lower word is read and when it is '1', the higher word is read.

# PIC24FJ128GB204 FAMILY

**FIGURE 4-8: DATA ACCESS FROM PROGRAM SPACE ADDRESS GENERATION**

## 4.3.2 DATA ACCESS FROM PROGRAM MEMORY USING TABLE INSTRUCTIONS

The TBLRDL and TBLWTL instructions offer a direct method of reading or writing the lower word of any address within the program space without going through Data Space. The TBLRDH and TBLWTH instructions are the only method to read or write the upper 8 bits of a program space word as data.

The PC is incremented by two for each successive 24-bit program word. This allows program memory addresses to directly map to Data Space addresses. Program memory can thus be regarded as two, 16-bit word-wide address spaces, residing side by side, each with the same address range. TBLRDL and TBLWTL access the space which contains the least significant data word, and TBLRDH and TBLWTH access the space which contains the upper data byte.

Two table instructions are provided to move byte or word-sized (16-bit) data to and from program space. Both function as either byte or word operations.

1. TBLRDL (Table Read Low): In Word mode, it maps the lower word of the program space location ( $P<15:0>$ ) to a data address ( $D<15:0>$ ). In Byte mode, either the upper or lower byte of the lower program word is mapped to the lower byte of a data address. The upper byte is selected when byte select is '1'; the lower byte is selected when it is '0'.

2. TBLRDH (Table Read High): In Word mode, it maps the entire upper word of a program address ( $P<23:16>$ ) to a data address. Note that  $D<15:8>$ , the 'phantom' byte, will always be '0'.

In Byte mode, it maps the upper or lower byte of the program word to  $D<7:0>$  of the data address, as above. Note that the data will always be '0' when the upper 'phantom' byte is selected (Byte Select = 1).

In a similar fashion, two table instructions, TBLWTH and TBLWTL, are used to write individual bytes or words to a program space address. The details of their operation are described in [Section 6.0 "Flash Program Memory"](#).

For all table operations, the area of program memory space to be accessed is determined by the Table Memory Page Address register (TBLPAG). TBLPAG covers the entire program memory space of the device, including user and configuration spaces. When  $TBLPAG<7> = 0$ , the table page is located in the user memory space. When  $TBLPAG<7> = 1$ , the page is located in configuration space.

**Note:** Only Table Read operations will execute in the configuration memory space where Device IDs are located; Table Write operations are not allowed.

**FIGURE 4-9: ACCESSING PROGRAM MEMORY WITH TABLE INSTRUCTIONS**

# PIC24FJ128GB204 FAMILY

## 4.3.3 READING DATA FROM PROGRAM MEMORY USING EDS

The upper 32 Kbytes of Data Space may optionally be mapped into any 16K word page of the program space. This provides transparent access of stored constant data from the Data Space without the need to use special instructions (i.e., TBLRDL/H).

Program space access through the Data Space occurs when the MSb of EA is '1' and the DSRPAG<9> bit is also '1'. The lower 8 bits of DSRPAG are concatenated to the Wn<14:0> bits to form a 23-bit EA to access program memory. The DSRPAG<8> bit decides which word should be addressed; when the bit is '0', the lower word and when '1', the upper word of the program memory is accessed.

The entire program memory is divided into 512 EDS pages, from 200h to 3FFh, each consisting of 16K words of data. Pages, 200h to 2FFh, correspond to the lower words of the program memory, while 300h to 3FFh correspond to the upper words of the program memory.

Using this EDS technique, the entire program memory can be accessed. Previously, the access to the upper word of the program memory was not supported.

Table 4-37 provides the corresponding 23-bit EDS address for program memory with EDS page and source addresses.

For operations that use PSV and are executed outside a REPEAT loop, the MOV and MOV.D instructions will require one instruction cycle in addition to the specified execution time. All other instructions will require two instruction cycles in addition to the specified execution time.

For operations that use PSV, which are executed inside a REPEAT loop, there will be some instances that require two instruction cycles in addition to the specified execution time of the instruction:

- Execution in the first iteration
- Execution in the last iteration
- Execution prior to exiting the loop due to an interrupt
- Execution upon re-entering the loop after an interrupt is serviced

Any other iteration of the REPEAT loop will allow the instruction accessing data, using PSV, to execute in a single cycle.

TABLE 4-37: EDS PROGRAM ADDRESS WITH DIFFERENT PAGES AND ADDRESSES

DSRPAG (Data Space Read Register)	Source Address while Indirect Addressing	23-Bit EA Pointing to EDS	Comment
200h • • • 2FFh		000000h to 007FFEh • • 7F8000h to 7FFFFFFh	Lower words of 4M program instructions (8 Mbytes); for read operations only
300h • • • 3FFh	8000h to FFFFh	000001h to 007FFFFh • • 7F8001h to 7FFFFFFh	Upper words of 4M program instructions (4 Mbytes remaining, 4 Mbytes are phantom bytes); for read operations only
000h		Invalid Address	Address error trap <sup>(1)</sup>

Note 1: When the source/destination address is above 8000h and DSRPAG/DSWPAG is '0', an address error trap will occur.

## EXAMPLE 4-3: EDS READ CODE FROM PROGRAM MEMORY IN ASSEMBLY

```
; Set the EDS page from where the data to be read
    mov     #0x0202, w0
    mov     w0, DSRPAG           ;page 0x202, consisting lower words, is selected for read
    mov     #0x000A, w1           ;select the location (0x0A) to be read
    bset    w1, #15              ;set the MSB of the base address, enable EDS mode

;Read a byte from the selected location
    mov.b   [w1++], w2          ;read Low byte
    mov.b   [w1++], w3          ;read High byte

;Read a word from the selected location
    mov     [w1], w2             ;
;Read Double - word from the selected location
    mov.d   [w1], w2             ;two word read, stored in w2 and w3

**NOTES:**

## 5.0 DIRECT MEMORY ACCESS CONTROLLER (DMA)

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the "dsPIC33/PIC24 Family Reference Manual", "Direct Memory Access Controller (DMA)" (DS39742). The information in this data sheet supersedes the information in the FRM.

The Direct Memory Access Controller (DMA) is designed to service high data throughput peripherals operating on the SFR bus, allowing them to access data memory directly and alleviating the need for CPU-intensive management. By allowing these data-intensive peripherals to share their own data path, the main data bus is also deloaded, resulting in additional power savings.

The DMA Controller functions both as a peripheral and a direct extension of the CPU. It is located on the microcontroller data bus between the CPU and DMA-enabled peripherals, with direct access to SRAM. This partitions the SFR bus into two buses, allowing the DMA Controller access to the DMA capable peripherals located on the new DMA SFR bus. The controller serves as a master device on the DMA SFR bus, controlling data flow from DMA capable peripherals.

The controller also monitors CPU instruction processing directly, allowing it to be aware of when the CPU requires access to peripherals on the DMA bus and automatically relinquishing control to the CPU as needed. This increases the effective bandwidth for handling data without DMA operations causing a processor stall. This makes the controller essentially transparent to the user.

The DMA Controller has these features:

- Six multiple independent and independently programmable channels
- Concurrent operation with the CPU (no DMA caused Wait states)
- DMA bus arbitration
- Five Programmable Address modes
- Four Programmable Transfer modes
- Four Flexible Internal Data Transfer modes
- Byte or word support for data transfer
- 16-Bit Source and Destination Address register for each channel, dynamically updated and reloadable
- 16-Bit Transaction Count register, dynamically updated and reloadable
- Upper and Lower Address Limit registers
- Counter half-full level interrupt
- Software-triggered transfer
- Null Write mode for symmetric buffer operations

A simplified block diagram of the DMA Controller is shown in [Figure 5-1](#).

**FIGURE 5-1: DMA FUNCTIONAL BLOCK DIAGRAM**

# PIC24FJ128GB204 FAMILY

---

## 5.1 Summary of DMA Operations

The DMA Controller is capable of moving data between addresses according to a number of different parameters. Each of these parameters can be independently configured for any transaction. In addition, any or all of the DMA channels can independently perform a different transaction at the same time. Transactions are classified by these parameters:

- Source and destination (SFRs and data RAM)
- Data size (byte or word)
- Trigger source
- Transfer mode (One-Shot, Repeated or Continuous)
- Addressing modes (Fixed Address or Address Blocks with or without Address Increment/Decrement)

In addition, the DMA Controller provides channel priority arbitration for all channels.

### 5.1.1 SOURCE AND DESTINATION

Using the DMA Controller, data may be moved between any two addresses in the Data Space. The SFR space (0000h to 07FFh), or the data RAM space (0800h to FFFFh) can serve as either the source or the destination. Data can be moved between these areas in either direction, or between addresses in either area. The four different combinations are shown in [Figure 5-2](#).

If it is necessary to protect areas of data RAM, the DMA Controller allows the user to set upper and lower address boundaries for operations in the Data Space above the SFR space. The boundaries are set by the DMAH and DMAL High/Low Address Limit registers. If a DMA channel attempts an operation outside of the address boundaries, the transaction is terminated and an interrupt is generated.

### 5.1.2 DATA SIZE

The DMA Controller can handle both 8-bit and 16-bit transactions. Size is user-selectable using the SIZE bit (DMACHn<1>). By default, each channel is configured for word-size transactions. When byte-size transactions are chosen, the LSb of the source and/or destination address determines if the data represents the upper or lower byte of the data RAM location.

### 5.1.3 TRIGGER SOURCE

The DMA Controller can use 63 of the device's interrupt sources to initiate a transaction. The DMA trigger sources occur in reverse order than their natural interrupt priority and are shown in [Table 5-1](#).

These sources cannot be used as DMA triggers:

- Input Capture 8 and 9
- Output Compare 7, 8 and 9
- USB

Since the source and destination addresses for any transaction can be programmed independently of the trigger source, the DMA Controller can use any trigger to perform an operation on any peripheral. This also allows DMA channels to be cascaded to perform more complex transfer operations.

### 5.1.4 TRANSFER MODE

The DMA Controller supports four types of data transfers, based on the volume of data to be moved for each trigger:

- One-Shot: A single transaction occurs for each trigger.
- Continuous: A series of back-to-back transactions occur for each trigger; the number of transactions is determined by the DMACNTn transaction counter.
- Repeated One-Shot: A single transaction is performed repeatedly, once per trigger, until the DMA channel is disabled.
- Repeated Continuous: A series of transactions are performed repeatedly, one cycle per trigger, until the DMA channel is disabled.

All Transfer modes allow the option to have the source and destination addresses, and counter value automatically reloaded after the completion of a transaction; Repeated mode transfers do this automatically.

### 5.1.5 ADDRESSING MODES

The DMA Controller also supports transfers between single addresses or address ranges. The four basic options are:

- Fixed-to-Fixed: Between two constant addresses
- Fixed-to-Block: From a constant source address to a range of destination addresses
- Block-to-Fixed: From a range of source addresses to a single, constant destination address
- Block-to-Block: From a range of source addresses to a range of destination addresses

The option to select auto-increment or auto-decrement of source and/or destination addresses is available for Block Addressing modes.

In addition to the four basic modes, the DMA Controller also supports Peripheral Indirect Addressing (PIA) mode, where the source or destination address is generated jointly by the DMA Controller and a PIA capable peripheral. When enabled, the DMA channel provides a base source and/or destination address, while the peripheral provides a fixed range offset address.

For PIC24FJ128GB204 family devices, the 12-bit A/D Converter module is the only PIA capable peripheral. Details for its use in PIA mode are provided in [Section 25.0 “12-Bit A/D Converter with Threshold Detect”](#).

---

## 5.1.6 CHANNEL PRIORITY

Each DMA channel functions independently of the others, but also competes with the others for access to the data and DMA buses. When access collisions occur, the DMA Controller arbitrates between the channels using a user-selectable priority scheme. Two schemes are available:

- Round Robin: When two or more channels collide, the lower numbered channel receives priority on the first collision. On subsequent collisions, the higher numbered channels each receive priority based on their channel number.
- Fixed Priority: When two or more channels collide, the lowest numbered channel always receives priority, regardless of past history.

## 5.2 Typical Setup

To set up a DMA channel for a basic data transfer:

1. Enable the DMA Controller (DMAEN = 1) and select an appropriate channel priority scheme by setting or clearing PRSSEL.
2. Program DMAH and DMAL with appropriate upper and lower address boundaries for data RAM operations.
3. Select the DMA channel to be used and disable its operation (CHEN = 0).
4. Program the appropriate source and destination addresses for the transaction into the channel's DMASRCn and DMADSTn registers. For PIA Addressing mode, use the base address value.
5. Program the DMACNTn register for the number of triggers per transfer (One-Shot or Continuous modes) or the number of words (bytes) to be transferred (Repeated modes).
6. Set or clear the SIZE bit to select the data size.
7. Program the TRMODEEx bits to select the Data Transfer mode.
8. Program the SAMODEEx and DAMODEEx bits to select the addressing mode.
9. Enable the DMA channel by setting CHEN.
10. Enable the trigger source interrupt.

## 5.3 Peripheral Module Disable

Unlike other peripheral modules, the channels of the DMA Controller cannot be individually powered down using the Peripheral Module Disable x (PMDx) registers. Instead, the channels are controlled as two groups. The DMA0MD bit (PMD7<4>) selectively controls DMACH0 through DMACH3. The DMA1MD bit (PMD7<5>) controls DMACH4 and DMACH5. Setting both bits effectively disables the DMA Controller.

## 5.4 Registers

The DMA Controller uses a number of registers to control its operation. The number of registers depends on the number of channels implemented for a particular device.

There are always four module-level registers (one control and three buffer/address):

- DMACON: DMA Control Register ([Register 5-1](#))
- DMAH and DMAL: DMA High and Low Address Limit Registers
- DMABUF: DMA Transfer Data Buffer

Each of the DMA channels implements five registers (two control and three buffer/address):

- DMACHn: DMA Channel n Control Register ([Register 5-2](#))
- DMAINTn: DMA Channel n Interrupt Control Register ([Register 5-3](#))
- DMASRCn: DMA Channel Source Address Pointer for Channel n Register
- DMADSTn: DMA Destination Address for Channel n Register
- DMACNTn: DMA Transaction Count for Channel n Register

For PIC24FJ128GB204 family devices, there are a total of 34 registers.

## 6.0 FLASH PROGRAM MEMORY

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Program Memory” (DS39715). The information in this data sheet supersedes the information in the FRM.

The PIC24FJ128GB204 family of devices contains internal Flash program memory for storing and executing application code. The program memory is readable, writable and erasable. The Flash memory can be programmed in four ways:

- In-Circuit Serial Programming™ (ICSP™)
- Run-Time Self-Programming (RTSP)
- JTAG
- Enhanced In-Circuit Serial Programming (Enhanced ICSP)

ICSP allows a PIC24FJ128GB204 family device to be serially programmed while in the end application circuit. This is simply done with two lines for the programming clock and programming data (named PGECx and PGEDx, respectively), and three other lines for power (VDD), ground (Vss) and Master Clear (MCLR). This allows customers to manufacture boards with unprogrammed devices and then program the

microcontroller just before shipping the product. This also allows the most recent firmware or a custom firmware to be programmed.

RTSP is accomplished using TBLRD (Table Read) and TBLWT (Table Write) instructions. With RTSP, the user may write program memory data in blocks of 64 instructions (192 bytes) at a time and erase program memory in blocks of 512 instructions (1536 bytes) at a time.

## 6.1 Table Instructions and Flash Programming

Regardless of the method used, all programming of Flash memory is done with the Table Read and Table Write instructions. These allow direct read and write access to the program memory space from the data memory while the device is in normal operating mode. The 24-bit target address in the program memory is formed using the TBLPAG<7:0> bits and the Effective Address (EA) from a W register, specified in the table instruction, as shown in Figure 6-1.

The TBLRDL and the TBLWTL instructions are used to read or write to bits<15:0> of program memory. TBLRDL and TBLWTL can access program memory in both Word and Byte modes.

The TBLRDH and TBLWTH instructions are used to read or write to bits<23:16> of program memory. TBLRDH and TBLWTH can also access program memory in Word or Byte mode.

**FIGURE 6-1: ADDRESSING FOR TABLE REGISTERS**

# PIC24FJ128GB204 FAMILY

---

## 6.2 RTSP Operation

The PIC24F Flash program memory array is organized into rows of 64 instructions or 192 bytes. RTSP allows the user to erase blocks of eight rows (512 instructions) at a time and to program one row at a time. It is also possible to program single words.

The 8-row erase blocks and single row write blocks are edge-aligned, from the beginning of program memory on boundaries of 1536 bytes and 192 bytes, respectively.

When data is written to program memory using TBLWT instructions, the data is not written directly to memory. Instead, data written using Table Writes is stored in holding latches until the programming sequence is executed.

Any number of TBLWT instructions can be executed and a write will be successfully performed. However, 64 TBLWT instructions are required to write the full row of memory.

To ensure that no data is corrupted during a write, any unused address should be programmed with FFFFFFh. This is because the holding latches reset to an unknown state, so if the addresses are left in the Reset state, they may overwrite the locations on rows which were not rewritten.

The basic sequence for RTSP programming is to set up a Table Pointer, then do a series of TBLWT instructions to load the buffers. Programming is performed by setting the control bits in the NVMCON register.

Data can be loaded in any order and the holding registers can be written to, multiple times, before performing a write operation. Subsequent writes, however, will wipe out any previous writes.

**Note:** Writing to a location multiple times, without erasing, is not recommended.

All of the Table Write operations are single-word writes (2 instruction cycles), because only the buffers are written. A programming cycle is required for programming each row.

## 6.3 JTAG Operation

The PIC24F family supports JTAG boundary scan. Boundary scan can improve the manufacturing process by verifying pin to PCB connectivity.

## 6.4 Enhanced In-Circuit Serial Programming

Enhanced In-Circuit Serial Programming uses an on-board bootloader, known as the Program Executive (PE), to manage the programming process. Using an SPI data frame format, the Program Executive can erase, program and verify program memory. For more information on Enhanced ICSP, see the device programming specification.

## 6.5 Control Registers

There are two SFRs used to read and write the program Flash memory: NVMCON and NVMKEY.

The NVMCON register ([Register 6-1](#)) controls which blocks are to be erased, which memory type is to be programmed and when the programming cycle starts.

NVMKEY is a write-only register that is used for write protection. To start a programming or erase sequence, the user must consecutively write 55h and AAh to the NVMKEY register. For more information, refer to [Section 6.6 “Programming Operations”](#).

## 6.6 Programming Operations

A complete programming sequence is necessary for programming or erasing the internal Flash in RTSP mode. During a programming or erase operation, the processor stalls (waits) until the operation is finished. Setting the WR bit (NVMCON<15>) starts the operation and the WR bit is automatically cleared when the operation is finished.

- bit 15      **WR:** Write Control bit<sup>(1)</sup>  
               1 = Initiates a Flash memory program or erase operation; the operation is self-timed and the bit is cleared by hardware once the operation is complete  
               0 = Program or erase operation is complete and inactive
- bit 14      **WREN:** Write Enable bit<sup>(1)</sup>  
               1 = Enables Flash program/erase operations  
               0 = Inhibits Flash program/erase operations
- bit 13      **WRERR:** Write Sequence Error Flag bit<sup>(1)</sup>  
               1 = An improper program or erase sequence attempt, or termination has occurred (bit is set automatically on any set attempt of the WR bit)  
               0 = The program or erase operation completed normally
- bit 12-7     **Unimplemented:** Read as '0'
- bit 6        **ERASE:** Erase/Program Enable bit<sup>(1)</sup>  
               1 = Performs the erase operation specified by the NVMOP<3:0> bits on the next WR command  
               0 = Performs the program operation specified by the NVMOP<3:0> bits on the next WR command
- bit 5-4      **Unimplemented:** Read as '0'
- bit 3-0      **NVMOP<3:0>:** NVM Operation Select bits<sup>(1,2)</sup>  
               1111 = Memory bulk erase operation (ERASE = 1) or no operation (ERASE = 0)<sup>(3)</sup>  
               0011 = Memory word program operation (ERASE = 0) or no operation (ERASE = 1)  
               0010 = Memory page erase operation (ERASE = 1) or no operation (ERASE = 0)  
               0001 = Memory row program operation (ERASE = 0) or no operation (ERASE = 1)

**Note 1:** These bits can only be reset on a Power-on Reset.

**2:** All other combinations of NVMOP<3:0> are unimplemented.

**3:** Available in ICSP™ mode only; refer to the device programming specification.

# PIC24FJ128GB204 FAMILY

## 6.6.1 PROGRAMMING ALGORITHM FOR FLASH PROGRAM MEMORY

The user can program one row of Flash program memory at a time. To do this, it is necessary to erase the 8-row erase block containing the desired row. The general process is:

1. Read eight rows of program memory (512 instructions) and store in data RAM.
2. Update the program data in RAM with the desired new data.
3. Erase the block (see [Example 6-1](#)):
  - a) Set the NVMOPx bits (NVMCON<3:0>) to '0010' to configure for block erase. Set the ERASE (NVMCON<6>) and WREN (NVMCON<14>) bits.
  - b) Write the starting address of the block to be erased into the TBLPAG and W registers.
  - c) Write 55h to NVMKEY.
  - d) Write AAh to NVMKEY.
  - e) Set the WR bit (NVMCON<15>). The erase cycle begins and the CPU stalls for the duration of the erase cycle. When the erase is done, the WR bit is cleared automatically.

4. Write the first 64 instructions from data RAM into the program memory buffers (see [Example 6-3](#)).
5. Write the program block to Flash memory:
  - a) Set the NVMOPx bits to '0001' to configure for row programming. Clear the ERASE bit and set the WREN bit.
  - b) Write 55h to NVMKEY.
  - c) Write AAh to NVMKEY.
  - d) Set the WR bit. The programming cycle begins and the CPU stalls for the duration of the write cycle. When the write to Flash memory is done, the WR bit is cleared automatically.
6. Repeat Steps 4 and 5, using the next available 64 instructions from the block in data RAM by incrementing the value in TBLPAG, until all 512 instructions are written back to Flash memory.

For protection against accidental operations, the write initiate sequence for NVMKEY must be used to allow any erase or program operation to proceed. After the programming command has been executed, the user must wait for the programming time until programming is complete. The two instructions following the start of the programming sequence should be NOPs, as shown in [Example 6-4](#).

## EXAMPLE 6-1: ERASING A PROGRAM MEMORY BLOCK (ASSEMBLY LANGUAGE CODE)

```
; Set up NVMCON for block erase operation
    MOV     #0x4042, W0
    MOV     W0, NVMCON
; Initialize NVMCON
; Initialize Program Memory (PM) Page Boundary SFR
; Initialize in-page EA<15:0> pointer
; Set base address of erase block
; Block all interrupts with priority <7
; for next 5 instructions
;
; Write the 0x55 key
;
; Write the 0xAA key
;
; Start the erase sequence
; Insert two NOPs after the erase
; command is asserted
;
```

# PIC24FJ128GB204 FAMILY

## EXAMPLE 6-2: ERASING A PROGRAM MEMORY BLOCK ('C' LANGUAGE CODE)

```
// C example using MPLAB C30
unsigned long progAddr = 0xFFFFFFFF;           // Address of row to write
unsigned int offset;
//Set up pointer to the first memory location to be written
TBLPAG = progAddr>>16;                      // Initialize PM Page Boundary SFR
offset = progAddr & 0xFFFF;                     // Initialize lower word of address
__builtin_tblwtl(offset, 0x0000);               // Set base address of erase block
                                                // with dummy latch write
NVMCON = 0x4042;                             // Initialize NVMCON
asm("DISI #5");                            // Block all interrupts with priority <7
                                            // for next 5 instructions
__builtin_write_NVM();                         // check function to perform unlock
                                                // sequence and set WR
```

## EXAMPLE 6-3: LOADING THE WRITE BUFFERS

```
; Set up NVMCON for row programming operations
    MOV    #0x4001, W0          ;
    MOV    W0, NVMCON          ; Initialize NVMCON
; Set up a pointer to the first program memory location to be written
; program memory selected, and writes enabled
    MOV    #0x0000, W0          ;
    MOV    W0, TBLPAG          ; Initialize PM Page Boundary SFR
    MOV    #0x6000, W0          ; An example program memory address
; Perform the TBLWT instructions to write the latches
; 0th_program_word
    MOV    #LOW_WORD_0, W2      ;
    MOV    #HIGH_BYTE_0, W3     ;
    TBLWTL W2, [W0]            ; Write PM low word into program latch
    TBLWTH W3, [W0++]          ; Write PM high byte into program latch
; 1st_program_word
    MOV    #LOW_WORD_1, W2      ;
    MOV    #HIGH_BYTE_1, W3     ;
    TBLWTL W2, [W0]            ; Write PM low word into program latch
    TBLWTH W3, [W0++]          ; Write PM high byte into program latch
; 2nd_program_word
    MOV    #LOW_WORD_2, W2      ;
    MOV    #HIGH_BYTE_2, W3     ;
    TBLWTL W2, [W0]            ; Write PM low word into program latch
    TBLWTH W3, [W0++]          ; Write PM high byte into program latch
    .
    .
    .
; 63rd_program_word
    MOV    #LOW_WORD_63, W2     ;
    MOV    #HIGH_BYTE_63, W3     ;
    TBLWTL W2, [W0]            ; Write PM low word into program latch
    TBLWTH W3, [W0]            ; Write PM high byte into program latch
```

## EXAMPLE 6-4: INITIATING A PROGRAMMING SEQUENCE

```
DISI    #5                  ; Block all interrupts with priority <7
                                                ; for next 5 instructions
MOV.B   #0x55, W0            ;
MOV    W0, NVMKEY            ; Write the 0x55 key
MOV.B   #0xAA, W1            ;
MOV    W1, NVMKEY            ; Write the 0xAA key
BSET    NVMCON, #WR          ; Start the programming sequence
NOP                 ;
NOP                 ;
BTSC    NVMCON, #15          ; and wait for it to be
BRA    $-2                  ; completed
```

# PIC24FJ128GB204 FAMILY

## 6.6.2 PROGRAMMING A SINGLE WORD OF FLASH PROGRAM MEMORY

If a Flash location has been erased, it can be programmed using Table Write instructions to write an instruction word (24-bit) into the write latch. The TBLPAG register is loaded with the 8 Most Significant Bytes (MSBs) of the Flash address. The TBLWTL and TBLWTH instructions write the desired data into the write latches and specify the lower 16 bits of the

program memory address to write to. To configure the NVMCON register for a word write, set the NVMOPx bits (NVMCON<3:0>) to '0011'. The write is performed by executing the unlock sequence and setting the WR bit (see [Example 6-5](#)). An equivalent procedure in 'C' compiler language, using the MPLAB® C30 compiler and built-in hardware functions, is shown in [Example 6-6](#).

### EXAMPLE 6-5: PROGRAMMING A SINGLE WORD OF FLASH PROGRAM MEMORY

```
; Setup a pointer to data Program Memory
MOV    #tblpage(PROG_ADDR), W0          ;
MOV    W0, TBLPAG                      ;Initialize PM Page Boundary SFR
MOV    #tbloffset(PROG_ADDR), W0        ;Initialize a register with program memory address

MOV    #LOW_WORD_N, W2                 ;
MOV    #HIGH_BYTE_N, W3                 ;
TBLWTL W2, [W0]                      ; Write PM low word into program latch
TBLWTH W3, [W0++]                     ; Write PM high byte into program latch

; Setup NVMCON for programming one word to data Program Memory
MOV    #0x4003, W0          ;
MOV    W0, NVMCON                  ; Set NVMOP bits to 0011

DISI   #5                         ; Disable interrupts while the KEY sequence is written
MOV.B #0x55, W0                   ; Write the key sequence
MOV    W0, NVMKEY
MOV.B #0xAA, W0
MOV    W0, NVMKEY
BSET   NVMCON, #WR              ; Start the write cycle
NOP                           ; Required delays
NOP
```

### EXAMPLE 6-6: PROGRAMMING A SINGLE WORD OF FLASH PROGRAM MEMORY ('C' LANGUAGE CODE)

```
// C example using MPLAB C30
unsigned int offset;
unsigned long progAddr = 0xFFFFFFFF;           // Address of word to program
unsigned int progDataL = 0xFFFF;                // Data to program lower word
unsigned char progDataH = 0xFF;                 // Data to program upper byte

//Set up NVMCON for word programming
NVMCON = 0x4003;                            // Initialize NVMCON

//Set up pointer to the first memory location to be written
TBLPAG = progAddr>>16;                      // Initialize PM Page Boundary SFR
offset = progAddr & 0xFFFF;                    // Initialize lower word of address

//Perform TBLWT instructions to write latches
__builtin_tblwtl(offset, progDataL);           // Write to address low word
__builtin_tblwth(offset, progDataH);            // Write to upper byte
asm("DISI #5");                             // Block interrupts with priority <7
                                              // for next 5 instructions
__builtin_write_NVM();                        // C30 function to perform unlock
                                              // sequence and set WR
```

## 7.0 RESETS

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Reset” (DS39712). The information in this data sheet supersedes the information in the FRM.

The Reset module combines all Reset sources and controls the device Master Reset Signal, SYSRST. The following is a list of device Reset sources:

- POR: Power-on Reset
- MCLR: Master Clear Pin Reset
- SWR: RESET Instruction
- WDT: Watchdog Timer Reset
- BOR: Brown-out Reset
- CM: Configuration Mismatch Reset
- TRAPR: Trap Conflict Reset
- IOPUWR: Illegal Opcode Reset
- UWR: Uninitialized W Register Reset

A simplified block diagram of the Reset module is shown in [Figure 7-1](#).

Any active source of Reset will make the SYSRST signal active. Many registers associated with the CPU and peripherals are forced to a known Reset state. Most registers are unaffected by a Reset; their status is unknown on POR and unchanged by all other Resets.

**Note:** Refer to the specific peripheral or CPU section of this manual for register Reset states.

All types of device Reset will set a corresponding status bit in the RCON register to indicate the type of Reset (see [Register 7-1](#)). In addition, Reset events occurring while an extreme power-saving feature is in use (such as VBAT) will set one or more status bits in the RCON register ([Register 7-2](#)). A POR will clear all bits, except for the BOR and POR (RCON<1:0>) bits, which are set. The user may set or clear any bit at any time during code execution. The RCON bits only serve as status bits. Setting a particular Reset status bit in software will not cause a device Reset to occur.

The RCON register also has other bits associated with the Watchdog Timer and device power-saving states. The function of these bits is discussed in other sections of this data sheet.

**Note:** The status bits in the RCON registers should be cleared after they are read so that the next RCON register values after a device Reset will be meaningful.

**FIGURE 7-1: RESET SYSTEM BLOCK DIAGRAM**

POR (RCON<0>)	POR	—

**Note:** All Reset flag bits may be set or cleared by the user software.

## 7.1 Special Function Register Reset States

Most of the Special Function Registers (SFRs) associated with the PIC24F CPU and peripherals are reset to a particular value at a device Reset. The SFRs are grouped by their peripheral or CPU function and their Reset values are specified in each section of this manual.

The Reset value for each SFR does not depend on the type of Reset, with the exception of four registers. The Reset value for the Reset Control register, RCON, will depend on the type of device Reset. The Reset value for the Oscillator Control register, OSCCON, will depend on the type of Reset and the programmed values of the FNOSC<sub>x</sub> bits in Flash Configuration Word 2 (CW2); see [Table 7-2](#). The RCFGCAL and NVMCON registers are only affected by a POR.

## 7.2 Device Reset Times

The Reset times for various types of device Reset are summarized in [Table 7-3](#). Note that the Master Reset Signal,  $\overline{\text{SYSRST}}$ , is released after the POR delay time expires.

The time at which the device actually begins to execute code will also depend on the system oscillator delays, which include the Oscillator Start-up Timer (OST) and the PLL lock time. The OST and PLL lock times occur in parallel with the applicable  $\overline{\text{SYSRST}}$  delay times.

The Fail-Safe Clock Monitor (FSCM) delay determines the time at which the FSCM begins to monitor the system clock source after the  $\overline{\text{SYSRST}}$  signal is released.

## 7.3 Brown-out Reset (BOR)

PIC24FJ128GB204 family devices implement a BOR circuit that provides the user with several configuration and power-saving options. The BOR is controlled by the BOREN (CW3<12>) Configuration bit.

When BOR is enabled, any drop of VDD below the BOR threshold results in a device BOR. Threshold levels are described in [Section 33.1 “DC Characteristics”](#) (Parameter DC17A).

## 7.4 Clock Source Selection at Reset

If clock switching is enabled, the system clock source at device Reset is chosen, as shown in [Table 7-2](#). If clock switching is disabled, the system clock source is always selected according to the Oscillator Configuration bits. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Oscillator” (DS39700).

**TABLE 7-2: OSCILLATOR SELECTION vs. TYPE OF RESET (CLOCK SWITCHING ENABLED)**

Reset Type	Clock Source Determinant
POR	FNOSC<2:0> Configuration bits (CW2<10:8>)
BOR	
MCLR	
WDTO	COSC<2:0> Control bits (OSCCON<14:12>)

Uninitialized W	Any Clock	TRST	—	<b>3</b>
Trap Conflict	Any Clock	TRST	—	<b>3</b>

**Note 1:** TPOR = Power-on Reset delay (10  $\mu$ s nominal).

**2:** TSTARTUP = TVREG.

**3:** TRST = Internal State Reset time (2  $\mu$ s nominal).

**4:** TOST = Oscillator Start-up Timer (OST). A 10-bit counter counts 1024 oscillator periods before releasing the oscillator clock to the system.

**5:** TLOCK = PLL lock time.

**6:** TFRC and TLPRC = RC Oscillator start-up times.

**7:** If Two-Speed Start-up is enabled, regardless of the Primary Oscillator selected, the device starts with FRC so the system clock delay is just TFRC, and in such cases, FRC start-up time is valid; it switches to the Primary Oscillator after its respective clock delay.

## 7.4.1 POR AND LONG OSCILLATOR START-UP TIMES

The oscillator start-up circuitry and its associated delay timers are not linked to the device Reset delays that occur at power-up. Some crystal circuits (especially low-frequency crystals) will have a relatively long start-up time. Therefore, one or more of the following conditions is possible after SYSRST is released:

- The oscillator circuit has not begun to oscillate.
- The Oscillator Start-up Timer has not expired (if a crystal oscillator is used).
- The PLL has not achieved a lock (if PLL is used).

The device will not begin to execute code until a valid clock source has been released to the system. Therefore, the oscillator and PLL start-up delays must be considered when the Reset delay time must be known.

## 7.4.2 FAIL-SAFE CLOCK MONITOR (FSCM) AND DEVICE RESETS

If the FSCM is enabled, it will begin to monitor the system clock source when SYSRST is released. If a valid clock source is not available at this time, the device will automatically switch to the FRC Oscillator and the user can switch to the desired crystal oscillator in the Trap Service Routine (TSR).

## 8.0 INTERRUPT CONTROLLER

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “*dsPIC33/PIC24 Family Reference Manual*”, “**Interrupts**” (DS70000600). The information in this data sheet supersedes the information in the FRM.

The PIC24F interrupt controller reduces the numerous peripheral interrupt request signals to a single interrupt request signal to the PIC24F CPU. It has the following features:

- Up to 8 processor exceptions and software traps
- Seven user-selectable priority levels
- Interrupt Vector Table (IVT) with up to 118 vectors
- Unique vector for each interrupt or exception source
- Fixed priority within a specified user priority level
- Alternate Interrupt Vector Table (AIVT) for debug support
- Fixed interrupt entry and return latencies

### 8.1 Interrupt Vector Table

The Interrupt Vector Table (IVT) is shown in [Figure 8-1](#). The IVT resides in program memory, starting at location, 0000004h. The IVT contains 126 vectors, consisting of 8 non-maskable trap vectors, plus up to 118 sources of interrupt. In general, each interrupt source has its own vector. Each interrupt vector contains a 24-bit wide address. The value programmed into each interrupt vector location is the starting address of the associated Interrupt Service Routine (ISR).

Interrupt vectors are prioritized in terms of their natural priority; this is linked to their position in the vector table. All other things being equal, lower addresses have a higher natural priority. For example, the interrupt associated with Vector 0 will take priority over interrupts at any other vector address.

PIC24FJ128GB204 family devices implement non-maskable traps and unique interrupts. These are summarized in [Table 8-1](#) and [Table 8-2](#).

### 8.1.1 ALTERNATE INTERRUPT VECTOR TABLE

The Alternate Interrupt Vector Table (AIVT) is located after the IVT, as shown in [Figure 8-1](#). The ALTIVT (INTCON2<15>) control bit provides access to the AIVT. If the ALTIVT bit is set, all interrupt and exception processes will use the alternate vectors instead of the default vectors. The alternate vectors are organized in the same manner as the default vectors.

The AIVT supports emulation and debugging efforts by providing a means to switch between an application and a support environment without requiring the interrupt vectors to be reprogrammed. This feature also enables switching between applications for evaluation of different software algorithms at run time. If the AIVT is not needed, the AIVT should be programmed with the same addresses used in the IVT.

## 8.2 Reset Sequence

A device Reset is not a true exception because the interrupt controller is not involved in the Reset process. The PIC24F devices clear their registers in response to a Reset, which forces the PC to zero. The microcontroller then begins program execution at location, 0000000h. The user programs a `GOTO` instruction at the Reset address, which redirects program execution to the appropriate start-up routine.

**Note:** Any unimplemented or unused vector locations in the IVT and AIVT should be programmed with the address of a default interrupt handler routine that contains a `RESET` instruction.

## 8.3 Interrupt Control and Status Registers

The PIC24FJ128GB204 family of devices implements a total of 43 registers for the interrupt controller:

- INTCON1
- INTCON2
- IFS0 through IFS7
- IEC0 through IEC7
- IPC0 through IPC16, IPC18 through IPC22, IPC26 and IPC29
- INTTREG

Global interrupt control functions are controlled from INTCON1 and INTCON2. INTCON1 contains the Interrupt Nesting Disable (NSTDIS) bit, as well as the control and status flags for the processor trap sources. The INTCON2 register controls the external interrupt request signal behavior and the use of the Alternate Interrupt Vector Table (AIVT).

The IFSx registers maintain all of the interrupt request flags. Each source of interrupt has a status bit, which is set by the respective peripherals or an external signal and is cleared via software.

The IECx registers maintain all of the interrupt enable bits. These control bits are used to individually enable interrupts from the peripherals or external signals.

The IPCx registers are used to set the Interrupt Priority Level (IPL) for each source of interrupt. Each user interrupt source can be assigned to one of eight priority levels.

The INTTREG register contains the associated interrupt vector number and the new CPU Interrupt Priority Level, which are latched into the Vector Number (VECNUM<7:0>) and the Interrupt Level (ILR<3:0>) bit fields in the INTTREG register. The new Interrupt Priority Level is the priority of the pending interrupt.

The interrupt sources are assigned to the IFSx, IECx and IPCx registers in the order of their vector numbers, as shown in [Table 8-2](#). For example, the INT0 (External Interrupt 0) is shown as having a vector number and a natural order priority of 0. Thus, the INT0IF status bit is found in IFS0<0>, the INT0IE enable bit in IEC0<0> and the INT0IP<2:0> priority bits in the first position of IPC0 (IPC0<2:0>).

Although they are not specifically part of the interrupt control hardware, two of the CPU Control registers contain bits that control interrupt functionality. The ALU STATUS Register (SR) contains the IPL<2:0> bits (SR<7:5>). These indicate the current CPU Interrupt Priority Level. The user can change the current CPU priority level by writing to the IPLx bits.

The CORCON register contains the IPL3 bit, which together with the IPL<2:0> bits, indicates the current CPU priority level. IPL3 is a read-only bit so that trap events cannot be masked by the user software.

The interrupt controller has the Interrupt Controller Test register, INTTREG, which displays the status of the interrupt controller. When an interrupt request occurs, its associated vector number and the new Interrupt Priority Level are latched into INTTREG. This information can be used to determine a specific interrupt source if a generic ISR is used for multiple vectors (such as when ISR remapping is used in bootloader applications) or to check if another interrupt is pending while in an ISR.

All Interrupt registers are described in [Register 8-1](#) through [Register 8-45](#) in the succeeding pages.

001 = CPU Interrupt Priority Level is 1 (9)

000 = CPU Interrupt Priority Level is 0 (8)

**Note 1:** See [Register 3-1](#) for the description of the remaining bits (bits 8, 4, 3, 2, 1 and 0) that are not dedicated to interrupt control functions.

**2:** The IPLx bits are concatenated with the IPL3 (CORCON<3>) bit to form the CPU Interrupt Priority Level. The value in parentheses indicates the Interrupt Priority Level if IPL3 = 1.

**3:** The IPLx bits are read-only when NSTDIS (INTCON1<15>) = 1.

- When VHOLD = 1:  
Indicates the vector number (from 0 to 118) of the last interrupt to occur.
- When VHOLD = 0:  
Indicates the vector number (from 0 to 118) of the interrupt request currently being handled.

## 8.4 Interrupt Setup Procedures

### 8.4.1 INITIALIZATION

To configure an interrupt source:

1. Set the NSTDIS (INTCON1<15>) control bit if nested interrupts are not desired.
2. Select the user-assigned priority level for the interrupt source by writing the control bits in the appropriate IPCx register. The priority level will depend on the specific application and type of interrupt source. If multiple priority levels are not desired, the IPCx register control bits for all enabled interrupt sources may be programmed to the same non-zero value.

**Note:** At a device Reset, the IPCx registers are initialized, such that all user interrupt sources are assigned to Priority Level 4.

3. Clear the interrupt flag status bit associated with the peripheral in the associated IFSx register.
4. Enable the interrupt source by setting the interrupt enable control bit associated with the source in the appropriate IECx register.

### 8.4.2 INTERRUPT SERVICE ROUTINE (ISR)

The method that is used to declare an Interrupt Service Routine (ISR) and initialize the IVT with the correct vector address will depend on the programming language (i.e., 'C' or assembler) and the language development toolsuite that is used to develop the application. In general, the user must clear the interrupt flag in the appropriate IFSx register for the source of the interrupt that the ISR handles; otherwise, the ISR will be re-entered immediately after exiting the routine. If the ISR is coded in assembly language, it must be terminated using a RETFIE instruction to unstack the saved PC value, SRL value and old CPU priority level.

### 8.4.3 TRAP SERVICE ROUTINE (TSR)

A Trap Service Routine (TSR) is coded like an ISR, except that the appropriate trap status flag in the INTCON1 register must be cleared to avoid re-entry into the TSR.

### 8.4.4 INTERRUPT DISABLE

All user interrupts can be disabled using the following procedure:

1. Push the current SR value onto the software stack using the PUSH instruction.
2. Force the CPU to Priority Level 7 by inclusive ORing the value, 0Eh, with SRL.

To enable user interrupts, the POP instruction may be used to restore the previous SR value.

Note that only user interrupts with a priority level of 7 or less can be disabled. Trap sources (Levels 8-15) cannot be disabled.

The DISI instruction provides a convenient way to disable interrupts of Priority Levels 1-6 for a fixed period of time. Level 7 interrupt sources are not disabled by the DISI instruction.

# **PIC24FJ128GB204 FAMILY**

---

---

**NOTES:**

## 9.0 OSCILLATOR CONFIGURATION

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Oscillator” (DS39700).

The oscillator system for PIC24FJ128GB204 family devices has the following features:

- A total of four external and internal oscillator options as clock sources, providing 15 different Clock modes
- An on-chip, USB PLL block to provide a stable 48 MHz clock for the USB module, as well as a range of frequency options for the system clock

- An on-chip PLL (x4, x6, x8) block available for the Primary Oscillator (POSC) source or FRCDIV (see [Section 9.8 “On-Chip PLL”](#))
- Software-controllable switching between various clock sources
- Software-controllable postscaler for selective clocking of CPU for system power savings
- A Fail-Safe Clock Monitor (FSCM) that detects clock failure and permits safe application recovery or shutdown
- A separate and independently configurable system clock output for synchronizing external hardware

A simplified diagram of the oscillator system is shown in [Figure 9-1](#).

**FIGURE 9-1: PIC24FJ128GB204 FAMILY CLOCK DIAGRAM**

# PIC24FJ128GB204 FAMILY

## 9.1 CPU Clocking Scheme

The system clock source can be provided by one of four sources:

- Primary Oscillator (POSC) on the OSC1 and OSC0 pins
- Secondary Oscillator (SOSC) on the SOSCI and SOSCO pins
- Fast Internal RC (FRC) Oscillator
- Low-Power Internal RC (LPRC) Oscillator

The Primary Oscillator and FRC sources have the option of using the internal USB PLL block, which generates both the USB module clock and a separate system clock from the 96 MHz PLL. Refer to [Section 9.6 “Oscillator Modes and USB Operation”](#) for additional information.

The internal FRC provides an 8 MHz clock source. It can optionally be reduced by the programmable clock divider to provide a range of system clock frequencies.

The selected clock source generates the processor and peripheral clock sources. The processor clock source is divided by two to produce the internal instruction cycle clock,  $F_{CY}$ . In this document, the instruction cycle clock is also denoted by  $F_{osc}/2$ . The internal instruction cycle clock,  $F_{osc}/2$ , can be provided on the OSC0 I/O pin for some operating modes of the Primary Oscillator.

## 9.2 Initial Configuration on POR

The oscillator source (and operating mode) that is used at a device Power-on Reset event is selected using Configuration bit settings. The Oscillator Configuration bit settings are located in the Configuration registers in program memory (for more information, refer to [Section 30.1 “Configuration Bits”](#)). The Primary Oscillator Configuration bits, POSCMD<1:0> (Configuration Word 2<1:0>), and the Initial Oscillator Select Configuration bits, FNOSC<2:0> (Configuration Word 2<10:8>), select the oscillator source that is used at a Power-on Reset. The FRC Primary Oscillator with Postscaler (FRCDIV) is the default (unprogrammed) selection. The Secondary Oscillator, or one of the internal oscillators, may be chosen by programming these bit locations.

The Configuration bits allow users to choose between the various clock modes, as shown in [Table 9-1](#).

### 9.2.1 CLOCK SWITCHING MODE CONFIGURATION BITS

The FCKSM<1:0> Configuration bits (Configuration Word 2<7:6>) are used to jointly configure device clock switching and the Fail-Safe Clock Monitor (FSCM). Clock switching is enabled only when FCKSM1 is programmed ('0'). The FSCM is enabled only when FCKSM<1:0> are both programmed ('00').

**TABLE 9-1: CONFIGURATION BIT VALUES FOR CLOCK SELECTION**

Oscillator Mode	Oscillator Source	POSCMD<1:0>	FNOSC<2:0>	Notes
Fast RC Oscillator with Postscaler (FRCDIV)	Internal	11	111	<a href="#">1, 2</a>
(Reserved)	Internal	xx	110	<a href="#">1</a>
Low-Power RC Oscillator (LPRC)	Internal	11	101	<a href="#">1</a>
Secondary (Timer1) Oscillator (SOSC)	Secondary	11	100	<a href="#">1</a>
Primary Oscillator (XT) with PLL Module (XTPLL)	Primary	01	011	
Primary Oscillator (EC) with PLL Module (ECPLL)	Primary	00	011	
Primary Oscillator (HS)	Primary	10	010	
Primary Oscillator (XT)	Primary	01	010	
Primary Oscillator (EC)	Primary	00	010	
Fast RC Oscillator with PLL Module (FRCPPLL)	Internal	11	001	<a href="#">1</a>
Fast RC Oscillator (FRC)	Internal	11	000	<a href="#">1</a>

**Note 1:** OSC0 pin function is determined by the OSCIOFCN Configuration bit.

**2:** This is the default oscillator mode for an unprogrammed (erased) device.

## 9.3 Control Registers

The operation of the oscillator is controlled by three Special Function Registers:

- OSCCON
- CLKDIV
- OSCTUN

The OSCCON register ([Register 9-1](#)) is the main control register for the oscillator. It controls clock source switching and allows the monitoring of clock sources.

The CLKDIV register ([Register 9-2](#)) controls the features associated with Doze mode, as well as the postscaler for the FRC Oscillator.

The OSCTUN register ([Register 9-3](#)) allows the user to fine-tune the FRC Oscillator over a range of approximately  $\pm 1.5\%$ . It also controls the FRC self-tuning features, described in [Section 9.5 “FRC Self-Tuning”](#).

### REGISTER 9-1: OSCCON: OSCILLATOR CONTROL REGISTER

## REGISTER 9-1: OSCCON: OSCILLATOR CONTROL REGISTER (CONTINUED)

bit 7	<b>CLKLOCK:</b> Clock Selection Lock Enable bit  <u>If FSCM is enabled (FCKSM1 = 1):</u> 1 = Clock and PLL selections are locked 0 = Clock and PLL selections are not locked and may be modified by setting the OSWEN bit <u>If FSCM is disabled (FCKSM1 = 0):</u> Clock and PLL selections are never locked and may be modified by setting the OSWEN bit.
bit 6	<b>IOLOCK:</b> I/O Lock Enable bit <sup>(2)</sup>  1 = I/O lock is active 0 = I/O lock is not active
bit 5	<b>LOCK:</b> PLL Lock Status bit <sup>(3)</sup>  1 = PLL module is in lock or PLL module start-up timer is satisfied 0 = PLL module is out of lock, PLL start-up timer is running or PLL is disabled
bit 4	<b>Unimplemented:</b> Read as '0'
bit 3	<b>CF:</b> Clock Fail Detect bit  1 = FSCM has detected a clock failure 0 = No clock failure has been detected
bit 2	<b>POSCEN:</b> Primary Oscillator (POSC) Sleep Enable bit  1 = Primary Oscillator continues to operate during Sleep mode 0 = Primary Oscillator is disabled during Sleep mode
bit 1	<b>SOSCEN:</b> 32 kHz Secondary Oscillator (SOSC) Enable bit  1 = Enables Secondary Oscillator 0 = Disables Secondary Oscillator
bit 0	<b>OSWEN:</b> Oscillator Switch Enable bit  1 = Initiates an oscillator switch to a clock source specified by the NOSC<2:0> bits 0 = Oscillator switch is complete

- Note 1:** Reset values for these bits are determined by the FNOSCx Configuration bits.  
**2:** The state of the IOLOCK bit can only be changed once an unlocking sequence has been executed. In addition, if the IOL1WAY Configuration bit is '1', once the IOLOCK bit is set, it cannot be cleared.  
**3:** This bit also resets to '0' during any valid clock switch or whenever a non-PLL Clock mode is selected.

111111 =  
•  
•  
•  
100001 =  
100000 = Minimum frequency deviation

**Note 1:** Use of either clock recovery source has specific application requirements. For more information, see [Section 9.5 "FRC Self-Tuning"](#).

## 9.4 Clock Switching Operation

With few limitations, applications are free to switch between any of the four clock sources (POSC, SOSC, FRC and LPRC) under software control and at any time. To limit the possible side effects that could result from this flexibility, PIC24F devices have a safeguard lock built into the switching process.

**Note:** The Primary Oscillator mode has three different submodes (XT, HS and EC) which are determined by the POSCMDx Configuration bits. While an application can switch to and from Primary Oscillator mode in software, it cannot switch between the different primary submodes without reprogramming the device.

### 9.4.1 ENABLING CLOCK SWITCHING

To enable clock switching, the FCKSM1 Configuration bit in CW2 must be programmed to '0'. (For more information, refer to [Section 30.1 "Configuration Bits"](#).) If the FCKSM1 Configuration bit is unprogrammed ('1'), the clock switching function and Fail-Safe Clock Monitor function are disabled; this is the default setting.

The NOSCx control bits (OSCCON<10:8>) do not control the clock selection when clock switching is disabled. However, the COSC<2:0> bits (OSCCON<14:12>) will reflect the clock source selected by the FNOSCx Configuration bits.

The OSWEN control bit (OSCCON<0>) has no effect when clock switching is disabled; it is held at '0' at all times.

### 9.4.2 OSCILLATOR SWITCHING SEQUENCE

At a minimum, performing a clock switch requires this basic sequence:

1. If desired, read the COSC<2:0> bits (OSCCON<14:12>) to determine the current oscillator source.
2. Perform the unlock sequence to allow a write to the OSCCON register high byte.
3. Write the appropriate value to the NOSCx bits (OSCCON<10:8>) for the new oscillator source.
4. Perform the unlock sequence to allow a write to the OSCCON register low byte.
5. Set the OSWEN bit to initiate the oscillator switch.

Once the basic sequence is completed, the system clock hardware responds automatically as follows:

1. The clock switching hardware compares the COSC<sub>x</sub> bits with the new value of the NOSC<sub>x</sub> bits. If they are the same, then the clock switch is a redundant operation. In this case, the OSWEN bit is cleared automatically and the clock switch is aborted.
2. If a valid clock switch has been initiated, the LOCK (OSCCON<5>) and CF (OSCCON<3>) bits are cleared.
3. The new oscillator is turned on by the hardware if it is not currently running. If a crystal oscillator must be turned on, the hardware will wait until the OST expires. If the new source is using the PLL, then the hardware waits until a PLL lock is detected (LOCK = 1).
4. The hardware waits for 10 clock cycles from the new clock source and then performs the clock switch.
5. The hardware clears the OSWEN bit to indicate a successful clock transition. In addition, the NOSC<sub>x</sub> bits value is transferred to the COSC<sub>x</sub> bits.
6. The old clock source is turned off at this time, with the exception of LPRC (if WDT or FSCM is enabled) or SOSC (if SOSCEN remains set).

**Note 1:** The processor will continue to execute code throughout the clock switching sequence. Timing-sensitive code should not be executed during this time.

**2:** Direct clock switches between any Primary Oscillator mode with PLL and FRCPLL mode are not permitted. This applies to clock switches in either direction. In these instances, the application must switch to FRC mode as a transitional clock source between the two PLL modes.

# PIC24FJ128GB204 FAMILY

A recommended code sequence for a clock switch includes the following:

1. Disable interrupts during the OSCCON register unlock and write sequence.
2. Execute the unlock sequence for the OSCCON high byte by writing 78h and 9Ah to OSCCON<15:8> in two back-to-back instructions.
3. Write new oscillator source to the NOSCx bits in the instruction immediately following the unlock sequence.
4. Execute the unlock sequence for the OSCCON low byte by writing 46h and 57h to OSCCON<7:0> in two back-to-back instructions.
5. Set the OSWEN bit in the instruction immediately following the unlock sequence.
6. Continue to execute code that is not clock-sensitive (optional).
7. Invoke an appropriate amount of software delay (cycle counting) to allow the selected oscillator and/or PLL to start and stabilize.
8. Check to see if OSWEN is '0'. If it is, the switch was successful. If OSWEN is still set, then check the LOCK bit to determine the cause of the failure.

The core sequence for unlocking the OSCCON register and initiating a clock switch is shown in [Example 9-1](#).

## EXAMPLE 9-1: BASIC CODE SEQUENCE FOR CLOCK SWITCHING

```
;Place the new oscillator selection in w0
;OSCCONH (high byte) Unlock Sequence
MOV      #OSCCONH, w1
MOV      #0x78, w2
MOV      #0x9A, w3
MOV.b   w2, [w1]
MOV.b   w3, [w1]
;Set new oscillator selection
MOV.b   WREG, OSCCONH
;OSCCONL (low byte) unlock sequence
MOV      #OSCCONL, w1
MOV      #0x46, w2
MOV      #0x57, w3
MOV.b   w2, [w1]
MOV.b   w3, [w1]
;Start oscillator switch operation
BSET    OSCCON, #0
```

## 9.5 FRC Self-Tuning

PIC24FJ128GB204 family devices include an automatic mechanism to calibrate the FRC during run time. This system uses clock recovery from a source of known accuracy to maintain the FRC within a very narrow margin of its nominal 8 MHz frequency. This allows for a frequency accuracy that exceeds 0.25%, which is well within the requirements of the “*USB 2.0 Specification*”.

**Note:** The self-tune feature maintains sufficient accuracy for operation in USB Device mode. For applications that function as a USB host, a high-accuracy clock source ( $\pm 0.05\%$ ) is still required.

The self-tune system is controlled by the bits in the upper half of the OSCTUN register. Setting the STEN bit (OSCTUN<15>) enables the system, causing it to recover a calibration clock from a source selected by the STSRC bit (OSCTUN<12>). When STSRC = 1, the system uses the Start-of-Frame (SOF) packets from an external USB host for its source. When STSRC = 0, the system uses the crystal controlled SOSC for its calibration source. Regardless of the source, the system uses the TUN<5:0> bits (OSCTUN<5:0>) to change the FRC’s frequency. Frequency monitoring and adjustment is dynamic, occurring continuously during run time. While the system is active, the TUNx bits cannot be written to by software.

**Note:** To use the USB as a clock recovery source (STSRC = 1), the microcontroller must be configured for USB operation and connected to an external USB device.

If the SOSC is to be used as the clock recovery source (STSRC = 0), the SOSC must always be enabled.

The self-tune system can generate a hardware interrupt, FSTIF. The interrupt can result from a drift of the FRC from the reference, by greater than 0.2%, in either direction or whenever the frequency deviation is beyond the ability of the TUNx bits to correct (i.e., greater than 1.5%). The STLOCK and STOR status bits (OSCTUN<11,9>) are used to indicate these conditions.

The STLPO and STORPOL bits (OSCTUN<10,8>) configure the FSTIF interrupt to occur in the presence or the absence of the conditions. It is the user’s responsibility to monitor both the STLOCK and STOR bits to determine the exact cause of the interrupt.

**Note:** The STLPO and STORPOL bits should be ignored when the self-tune system is disabled (STEN = 0).

## 9.6 Oscillator Modes and USB Operation

Because of the timing requirements imposed by USB, an internal clock of 48 MHz is required at all times while the USB module is enabled and not in a suspended operating state. Since this is well beyond the maximum CPU clock speed, a method is provided to internally generate both the USB and system clocks from a single oscillator source. PIC24FJ128GB204 family devices use the same clock structure as most other PIC24FJ devices, but include a two-branch PLL system to generate the two clock signals.

The USB PLL block is shown in [Figure 9-2](#). In this system, the input from the Primary Oscillator is divided down by a PLL prescaler to generate a 4 MHz output. This is used to drive an on-chip, 96 MHz PLL frequency multiplier to drive the two clock branches. One branch uses a fixed, divide-by-2 frequency divider to generate the 48 MHz USB clock. The other branch uses a fixed, divide-by-3 frequency divider and configurable PLL prescaler/divider to generate a range of system clock frequencies. The CPDIVx bits select the system clock speed. Available clock options are listed in [Table 9-2](#).

The USB PLL prescaler does not automatically sense the incoming oscillator frequency. The user must manually configure the PLL divider to generate the required 4 MHz output using the PLLDIV<3:0> Configuration bits. This limits the choices for Primary Oscillator frequency to a total of 8 possibilities, as shown in [Table 9-3](#).

**TABLE 9-2: SYSTEM CLOCK OPTIONS DURING USB OPERATION**

MCU Clock Division (CPDIV<1:0>)	Microcontroller Clock Frequency
None (00)	32 MHz
÷2 (01)	16 MHz
÷4 (10) <sup>(1)</sup>	8 MHz
÷8 (11) <sup>(1)</sup>	4 MHz

**Note 1:** Not compatible with USB operation; the USB module must be disabled to use this system clock option.

**TABLE 9-3: VALID PRIMARY OSCILLATOR CONFIGURATIONS FOR USB OPERATIONS**

Input Oscillator Frequency	Clock Mode	PLL Division (PLLDIV<3:0>)
48 MHz	ECPLL	÷12 (0111)
32 MHz	ECPLL	÷8 (0110)
24 MHz	HSPLL, ECPLL	÷6 (0101)
20 MHz	HSPLL, ECPLL	÷5 (0100)
16 MHz	HSPLL, ECPLL	÷4 (0011)
12 MHz	HSPLL, ECPLL	÷3 (0010)
8 MHz	ECPLL, XTPLL, FRCPLL <sup>(1)</sup>	÷2 (0001)
4 MHz	ECPLL, XTPLL, FRCPLL <sup>(1)</sup>	÷1 (0000)

**Note 1:** Requires the use of the FRC self-tune feature to maintain the required clock accuracy.

**FIGURE 9-2: USB PLL BLOCK**

# PIC24FJ128GB204 FAMILY

## 9.6.1 CONSIDERATIONS FOR USB OPERATION

When using the USB On-The-Go module in PIC24FJ128GB204 family devices, users must always observe these rules in configuring the system clock:

- The Oscillator modes listed in [Table 9-3](#) are the only oscillator configurations that permit USB operation. There is no provision to provide a separate external clock source to the USB module.
- For USB operation, the selected clock source (EC, HS or XT) must meet the USB clock tolerance requirements.
- When the FRCPLL Oscillator mode is used for USB applications, the FRC self-tune system should be used as well. While the FRC is accurate, the only two ways to ensure the level of accuracy required by the “*USB 2.0 Specification*”, throughout the application’s operating range, are either the self-tune system or manually changing the TUNx bits.
- The user must always ensure that the FRC source is configured to provide a frequency of 4 MHz or 8 MHz ( $RCDIV<2:0> = 001$  or  $000$ ) and that the USB PLL prescaler is configured appropriately.
- All other Oscillator modes are available; however, USB operation is not possible when these modes are selected. They may still be useful in cases where other power levels of operation are desirable and the USB module is not needed (for example, the application is Sleeping and waiting for a bus attachment).

## 9.7 Reference Clock Output

In addition to the CLKO output ( $F_{osc}/2$ ) available in certain Oscillator modes, the device clock in the PIC24FJ128GB204 family devices can also be configured to provide a reference clock output signal to a port pin. This feature is available in all oscillator configurations and allows the user to select a greater range of clock submultiples to drive external devices in the application.

This reference clock output is controlled by the REFOCONL, REFOCONH and REFOTRIML registers ([Register 9-4](#), [Register 9-5](#) and [Register 9-6](#)). Setting the ROEN bit ( $REFOCONL<15>$ ) enables the module. Setting the RROUT bit ( $REFOCONL<12>$ ) makes the clock signal available on the REFO pin.

The RODIVx bits ( $REFOCONH<14:0>$ ) enable the selection of 32768 different clock divider options.

### 9.7.1 CLOCK SOURCE REQUEST

The ROSELx bits determine different base clock sources for the module.

If the selected clock source has a global device enable (via device Configuration fuse settings), the user must enable the clock source before selecting it as a base clock source.

The ROACTIVE bit ( $REFOCONL<8>$ ) synchronizes the REFO module during the turn-on and turn-off of the module.

**Note:** Once the ROEN bit is set, it should not be cleared until the ROACTIVE bit is read as ‘1’.

## 9.7.2 CLOCK SWITCHING

The base clock to the module can be switched. First, turn off the module by clearing the ROEN bit ( $REFOCONL<15> = 0$ ) and wait for the ROACTIVE ( $REFOCONL<8>$ ) bit to be cleared by the hardware. This avoids a glitch in the REFO output.

The ROTRIMx and RODIVx bits can be changed on-the-fly. Follow the below mentioned steps before changing the ROTRIMx and RODIVx bits.

- REFO is not actively performing the divider switch ( $ROSWEN = 0$ ).
- Update the ROTRIMx and RODIVx bits with the latest values.
- Set the ROSWEN bit.
- Wait for the ROSWEN bit to be cleared by hardware.

The ROTRIMx bits allow a fractional divisor to be added to the integer divisor, specified in the RODIVx register bits.

### EQUATION 9-1: FRACTIONAL DIVISOR FOR ROTRIMx BITS

For  $RODIV<14:0> = 0$ , No Divide:

$RODIV<14:0> > 0$ , Period =  $2 * (RODIVx + ROTRIMx)$

## 9.7.3 OPERATION IN SLEEP MODE

The ROSLP and ROSELx bits ( $REFOCONL<11,3:0>$ ) control the availability of the reference output during Sleep mode.

The ROSLP bit determines if the reference source is available on the REFO pin when the device is in Sleep mode.

To use the reference clock output in Sleep mode, the ROSLP bit must be set and the reference base clock should not be the system clock or peripheral clock (ROSELx bits should not be ‘0b0000’ or ‘0b0001’).

The device clock must also be configured for either:

- One of the Primary modes (EC, HS or XT); the POSCEN bit should be set
- The Secondary Oscillator bit (SOSCEN) should be set
- The LPRC Oscillator

If one of the above conditions is not met, then the oscillators on OSC1, OSC2 and SOSCI will be powered down when the device enters Sleep mode.

000000001 = 1/512 (0.001953125) divisor added to RODIVx value

000000000 = 0/512 (0.0) divisor added to RODIV value

bit 6-0      **Unimplemented:** Read as '0'

## 9.8 On-Chip PLL

An on-chip PLL (x4, x6, x8) can be selected by the Configuration bits, PLLDIV<3:0>. The Primary Oscillator and FRC sources (FRCDIV) have the option of using this PLL.

Using the internal FRC source, the PLL module can generate the following frequencies, as shown in [Table 9-4](#).

**TABLE 9-4: VALID FRC CONFIGURATION FOR ON-CHIP PLL<sup>(1)</sup>**

FRC	RCDIV<2:0> (FRCDIV)	x4 PLL	x6 PLL	x8 PLL
8 MHz	000 (divide-by-1)	32 MHz	—	—
8 MHz	001 (divide-by-2)	16 MHz	24 MHz	32 MHz
8 MHz	010 (divide-by-4)	8 MHz	12 MHz	16 MHz

**Note 1:** The minimum frequency input to the on-chip PLL is 2 MHz.

**NOTES:**

## 10.0 POWER-SAVING FEATURES

**Note:** This data sheet summarizes the features of this group of PIC24FJ devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Power-Saving Features with Deep Sleep” (DS39727).

The PIC24FJ128GB204 family of devices provides the ability to manage power consumption by selectively managing clocking to the CPU and the peripherals. In general, a lower clock frequency and a reduction in the number of circuits being clocked reduces consumed power.

PIC24FJ128GB204 family devices manage power consumption with five strategies:

- Instruction-Based Power Reduction Modes
- Hardware-Based Power Reduction Features
- Clock Frequency Control
- Software Controlled Doze Mode
- Selective Peripheral Control in Software

Combinations of these methods can be used to selectively tailor an application’s power consumption, while still maintaining critical application features, such as timing-sensitive communications.

**TABLE 10-1: OPERATING MODES FOR PIC24FJ128GB204 FAMILY DEVICES**

Mode	Entry	Active Systems					DSGPR0/ DSGPR1 Retention
		Core	Peripherals	Data RAM Retention	RTCC <sup>(1)</sup>		
Run (default)	N/A	Y	Y	Y	Y	Y	Y
Idle	Instruction	N	Y	Y	Y	Y	Y
Sleep:							
Sleep	Instruction	N	S <sup>(2)</sup>	Y	Y	Y	Y
Low-Voltage Sleep	Instruction + RETEN bit	N	S <sup>(2)</sup>	Y	Y	Y	Y
Deep Sleep:							
Deep Sleep	Instruction + DSEN bit	N	N	N	Y	Y	Y
VBAT:							
with RTCC	Hardware	N	N	N	Y	Y	Y

**Note 1:** If RTCC is otherwise enabled in firmware.

**2:** A select peripheral can operate during this mode from LPRC or an external clock.

## 10.1 Overview of Power-Saving Modes

In addition to full-power operation, otherwise known as Run mode, the PIC24FJ128GB204 family of devices offers three instruction-based, power-saving modes and one hardware-based mode:

- Idle
- Sleep (Sleep and Low-Voltage Sleep)
- Deep Sleep
- VBAT (with and without RTCC)

All four modes can be activated by powering down different functional areas of the microcontroller, allowing progressive reductions of operating and Idle power consumption. In addition, three of the modes can be tailored for more power reduction at a trade-off of some operating features. [Table 10-1](#) lists all of the operating modes, in order of increasing power savings. [Table 10-2](#) summarizes how the microcontroller exits the different modes. Specific information is provided in the following sections.

# PIC24FJ128GB204 FAMILY

TABLE 10-2: EXITING POWER-SAVING MODES

Mode	Exit Conditions								Code Execution Resumes	
	Interrupts		Resets			RTCC Alarm	WDT	VDD Restore <sup>(2)</sup>		
	All	INT0	All	POR	MCLR					
Idle	Y	Y	Y	Y	Y	Y	Y	N/A	Next instruction	
Sleep (all modes)	Y	Y	Y	Y	Y	Y	Y	N/A		
Deep Sleep	N	Y	N	Y	Y	Y	Y <sup>(1)</sup>	N/A	Reset vector	
VBAT	N	N	N	N	N	N	N	Y	Reset vector	

**Note 1:** Deep Sleep WDT.

**2:** A POR or POR like Reset results whenever VDD is removed and restored in any mode except for Retention Deep Sleep.

## 10.1.1 INSTRUCTION-BASED POWER-SAVING MODES

Three of the power-saving modes are entered through the execution of the PWRSAV instruction. Sleep mode stops clock operation and halts all code execution. Idle mode halts the CPU and code execution, but allows peripheral modules to continue operation. Deep Sleep mode stops clock operation, code execution, and all peripherals, except RTCC and DSWDT. It also freezes I/O states and removes power to Flash memory, and may remove power to SRAM.

The assembly syntax of the PWRSAV instruction is shown in [Example 10-1](#). Sleep and Idle modes are entered directly with a single assembler command. Deep Sleep requires an additional sequence to unlock and enable the entry into Deep Sleep, which is described in [Section 10.4.1 “Entering Deep Sleep Mode”](#).

**Note:** SLEEP\_MODE and IDLE\_MODE are constants defined in the assembler include file for the selected device.

Sleep and Idle modes can be exited as a result of an enabled interrupt, WDT time-out or a device Reset. When the device exits these modes, it is said to “wake-up”.

### EXAMPLE 10-1: PWRSAV INSTRUCTION SYNTAX

```
// Syntax to enter Sleep mode:  
PWRSAV    #SLEEP_MODE      ; Put the device into SLEEP mode  
//  
//Syntax to enter Idle mode:  
PWRSAV    #IDLE_MODE       ; Put the device into IDLE mode  
//  
// Syntax to enter Deep Sleep mode:  
// First use the unlock sequence to set the DSEN bit (see Example 10-2)  
BSET     DSCON, #DSEN      ; Enable Deep Sleep  
BSET     DSCON, #DSEN      ; Enable Deep Sleep(repeat the command)  
PWRSAV    #SLEEP_MODE      ; Put the device into Deep SLEEP mode
```

The features enabled with the low-voltage/retention regulator results in some changes to the way that Sleep and Deep Sleep modes behave. See [Section 10.3 “Sleep Mode”](#) and [Section 10.4 “Deep Sleep Mode”](#) for additional information.

#### 10.1.1.1 Interrupts Coincident with Power Save Instructions

Any interrupt that coincides with the execution of a PWRSAV instruction will be held off until entry into Sleep or Idle mode has completed. The device will then wake-up from Sleep or Idle mode.

For Deep Sleep mode, interrupts that coincide with the execution of the PWRSAV instruction may be lost. If the low-voltage/retention regulator is not enabled, the microcontroller resets on leaving Deep Sleep and the interrupt will be lost.

Interrupts that occur during the Deep Sleep unlock sequence will interrupt the mandatory five-instruction cycle sequence timing and cause a failure to enter Deep Sleep. For this reason, it is recommended to disable all interrupts during the Deep Sleep unlock sequence.

## 10.1.2 HARDWARE-BASED POWER-SAVING MODE

The hardware-based VBAT mode does not require any action by the user during code development. Instead, it is a hardware design feature that allows the microcontroller to retain critical data (using the DSGPRx registers) and maintain the RTCC when VDD is removed from the application. This is accomplished by supplying a backup power source to a specific power pin. VBAT mode is described in more detail in [Section 10.5 “VBAT Mode”](#).

## 10.1.3 LOW-VOLTAGE/RETENTION REGULATOR

PIC24FJ128GB204 family devices incorporate a second on-chip voltage regulator, designed to provide power to select microcontroller features at 1.2V nominal. This regulator allows features, such as data RAM and the WDT, to be maintained in power-saving modes, where they would otherwise be inactive, or maintain them at a lower power than would otherwise be the case.

The low-voltage/retention regulator is only available when Sleep mode is invoked. It is controlled by the LPCFG Configuration bit (CW1<10>) and in firmware by the RETEN bit (RCON<12>). LPCFG must be programmed (= 0) and the RETEN bit must be set (= 1) for the regulator to be enabled.

## 10.2 Idle Mode

Idle mode includes these features:

- The CPU will stop executing instructions.
- The WDT is automatically cleared.
- The system clock source remains active. By default, all peripheral modules continue to operate normally from the system clock source, but can also be selectively disabled (see [Section 10.8 “Selective Peripheral Module Control”](#)).
- If the WDT or FSCM is enabled, the LPRC will also remain active.

The device will wake from Idle mode on any of these events:

- Any interrupt that is individually enabled
- Any device Reset
- A WDT time-out

On wake-up from Idle, the clock is reapplied to the CPU and instruction execution begins immediately, starting with the instruction following the PWRSAV instruction or the first instruction in the Interrupt Service Routine (ISR).

## 10.3 Sleep Mode

Sleep mode includes these features:

- The system clock source is shut down. If an on-chip oscillator is used, it is turned off.
- The device current consumption will be reduced to a minimum provided that no I/O pin is sourcing current.
- The I/O pin directions and states are frozen.
- The Fail-Safe Clock Monitor does not operate during Sleep mode since the system clock source is disabled.
- The LPRC clock will continue to run in Sleep mode if the WDT or RTCC, with LPRC as the clock source, is enabled.
- The WDT, if enabled, is automatically cleared prior to entering Sleep mode.
- Some device features or peripherals may continue to operate in Sleep mode. This includes items, such as the Input Change Notification on the I/O ports or peripherals that use an external clock input. Any peripheral that requires the system clock source for its operation will be disabled in Sleep mode.

The device will wake-up from Sleep mode on any of these events:

- On any interrupt source that is individually enabled
- On any form of device Reset
- On a WDT time-out

On wake-up from Sleep, the processor will restart with the same clock source that was active when Sleep mode was entered.

## 10.3.1 LOW-VOLTAGE/RETENTION SLEEP MODE

Low-Voltage/Retention Sleep mode functions as Sleep mode with the same features and wake-up triggers. The difference is that the low-voltage/retention regulator allows core digital logic voltage (VCORE) to drop to 1.2V nominal. This permits an incremental reduction of power consumption over what would be required if VCORE was maintained at a 1.8V (minimum) level.

Low-Voltage Sleep mode requires a longer wake-up time than Sleep mode, due to the additional time required to bring VCORE back to 1.8V (known as TREG). In addition, the use of the low-voltage/retention regulator limits the amount of current that can be sourced to any active peripherals, such as the RTCC, etc.

## 10.4 Deep Sleep Mode

Deep Sleep mode provides the lowest levels of power consumption available from the instruction-based modes.

Deep Sleep modes have these features:

- The system clock source is shut down. If an on-chip oscillator is used, it is turned off.
- The device current consumption will be reduced to a minimum.
- The I/O pin directions and states are frozen.
- The Fail-Safe Clock Monitor does not operate during Sleep mode since the system clock source is disabled.
- The LPRC clock will continue to run in Deep Sleep mode if the WDT, or RTCC with LPRC as the clock source, is enabled.
- The dedicated Deep Sleep WDT and BOR systems, if enabled, are used.
- The RTCC and its clock source continue to run, if enabled. All other peripherals are disabled.

Entry into Deep Sleep mode is completely under software control. Exit from the Deep Sleep modes can be triggered from any of the following events:

- POR event
- MCLR event
- RTCC alarm (If the RTCC is present)
- External Interrupt 0
- Deep Sleep Watchdog Timer (DSWDT) time-out

### 10.4.1 ENTERING DEEP SLEEP MODE

Deep Sleep mode is entered by setting the DSEN bit in the DS<sub>CON</sub> register and then executing a Sleep command (PWRS<sub>AV</sub> #SLEEP\_MODE), within one instruction cycle, to minimize the chance that Deep Sleep will be spuriously entered.

If the PWRS<sub>AV</sub> command is not given within one instruction cycle, the DSEN bit will be cleared by the hardware and must be set again by the software before entering Deep Sleep mode. The DSEN bit is also automatically cleared when exiting Deep Sleep mode.

**Note:** To re-enter Deep Sleep after a Deep Sleep wake-up, allow a delay of at least 3 T<sub>CY</sub> after clearing the RELEASE bit.

The sequence to enter Deep Sleep mode is:

1. If the application requires the Deep Sleep WDT, enable it and configure its clock source. For more information on Deep Sleep WDT, see [Section 10.4.5 “Deep Sleep WDT”](#).
2. If the application requires Deep Sleep BOR, enable it by programming the DSBOREN Configuration bit (CW4<6>).
3. If the application requires wake-up from Deep Sleep on RTCC alarm, enable and configure the RTCC module. For more information on RTCC, see [Section 22.0 “Real-Time Clock and Calendar \(RTCC\)”](#).
4. If needed, save any critical application context data by writing it to the DSGP<sub>R0</sub> and DSGP<sub>R1</sub> registers (optional).
5. Enable Deep Sleep mode by setting the DSEN bit (DS<sub>CON</sub><15>).

**Note:** A repeat sequence is required to set the DSEN bit. The repeat sequence (repeating the instruction twice) is required to write into any of the Deep Sleep registers (DS<sub>CON</sub>, DS<sub>WAKE</sub>, DSGP<sub>R0</sub>, DSGP<sub>R1</sub>). This is required to prevent the user from entering Deep Sleep by mistake. Any write to these registers has to be done twice to actually complete the write (see [Example 10-2](#)).

6. Enter Deep Sleep mode by issuing 3 NOP commands and then a PWRS<sub>AV</sub> #0 instruction.

Any time the DSEN bit is set, all bits in the DS<sub>WAKE</sub> register will be automatically cleared.

### EXAMPLE 10-2: THE REPEAT SEQUENCE

#### Example 1:

```
mov #8000, w2 ; enable DS
mov w2, DSCON
mov w2, DSCON ; second write required to
                  actually write to DSCON
```

#### Example 2:

```
bset DSCON, #15
nop
nop
nop
bset DSCON, #15 ; enable DS (two writes
                  required)
```

## 10.4.2 EXITING DEEP SLEEP MODES

Deep Sleep modes exit on any one of the following events:

- POR event on VDD supply. If there is no DSBOR circuit to re-arm the VDD supply POR circuit, the external VDD supply must be lowered to the natural arming voltage of the POR circuit.
- DSWDT time-out. When the DSWDT times out, the device exits Deep Sleep.
- RTCC alarm (if RTCEN = 1).
- Assertion ('0') of the MCLR pin.
- Assertion of the INT0 pin (if the interrupt was enabled before Deep Sleep mode was entered). The polarity configuration is used to determine the assertion level ('0' or '1') of the pin that will cause an exit from Deep Sleep mode. Exiting from Deep Sleep mode requires a change on the INT0 pin while in Deep Sleep mode.

**Note:** Any interrupt pending when entering Deep Sleep mode is cleared.

Exiting Deep Sleep generally does not retain the state of the device and is equivalent to a Power-on Reset (POR) of the device. Exceptions to this include the RTCC (if present), which remains operational through the wake-up, the DSGPRx registers and the DSWDT.

Wake-up events that occur from the time Deep Sleep exits, until the time the POR sequence completes, are not ignored. The DSWAKE register will capture ALL wake-up events, from setting the DSEN bit to clearing the RELEASE bit.

The sequence for exiting Deep Sleep mode is:

1. After a wake-up event, the device exits Deep Sleep and performs a POR. The DSEN bit is cleared automatically. Code execution resumes at the Reset vector.
2. To determine if the device exited Deep Sleep, read the Deep Sleep bit, DPSLP (RCON<10>). This bit will be set if there was an exit from Deep Sleep mode. If the bit is set, clear it.
3. Determine the wake-up source by reading the DSWAKE register.
4. Determine if a DSBOR event occurred during Deep Sleep mode by reading the DSBOR bit (DSCON<1>).
5. If application context data has been saved, read it back from the DSGPR0 and DSGPR1 registers.
6. Clear the RELEASE bit (DSCON<0>).

## 10.4.3 SAVING CONTEXT DATA WITH THE DSGPRx REGISTERS

As exiting Deep Sleep mode causes a POR, most Special Function Registers reset to their default POR values. In addition, because VCORE power is not supplied in Deep Sleep mode, information in data RAM may be lost when exiting this mode.

Applications which require critical data to be saved prior to Deep Sleep, may use the Deep Sleep General Purpose registers, DSGPR0 and DSGPR1, or data EEPROM (if available). Unlike other SFRs, the contents of these registers are preserved while the device is in Deep Sleep mode. After exiting Deep Sleep, software can restore the data by reading the registers and clearing the RELEASE bit (DSCON<0>).

**Note:** User software should enable the DSSWEN (CW4<8>) Configuration Fuse bit for saving critical data in the DSGPRx registers.

## 10.4.4 I/O PINS IN DEEP SLEEP MODES

During Deep Sleep, the general purpose I/O pins retain their previous states and the Secondary Oscillator (SOSC) will remain running, if enabled. Pins that are configured as inputs (TRISx bit set), prior to entry into Deep Sleep, remain high-impedance during Deep Sleep. Pins that are configured as outputs (TRISx bit clear), prior to entry into Deep Sleep, remain as output pins during Deep Sleep. While in this mode, they continue to drive the output level determined by their corresponding LATx bit at the time of entry into Deep Sleep.

Once the device wakes back up, all I/O pins continue to maintain their previous states, even after the device has finished the POR sequence and is executing application code again. Pins configured as inputs during Deep Sleep remain high-impedance and pins configured as outputs continue to drive their previous value. After waking up, the TRISx and LATx registers, and the SOSCEN bit (OSCCON<1>) are reset. If firmware modifies any of these bits or registers, the I/O will not immediately go to the newly configured states. Once the firmware clears the RELEASE bit (DSCON<0>), the I/O pins are "released". This causes the I/O pins to take the states configured by their respective TRISx and LATx bit values.

This means that keeping the SOSC running after waking up requires the SOSCEN bit to be set before clearing RELEASE.

If the Deep Sleep BOR (DSBOR) is enabled, and a DSBOR or a true POR event occurs during Deep Sleep, the I/O pins will be immediately released, similar to clearing the RELEASE bit. All previous state information will be lost, including the general purpose DSGPR0 and DSGPR1 contents.

# PIC24FJ128GB204 FAMILY

---

If a MCLR Reset event occurs during Deep Sleep, the DSGPRx, DSCON and DSWAKE registers will remain valid, and the RELEASE bit will remain set. The state of the SOSC will also be retained. The I/O pins, however, will be reset to their MCLR Reset state. Since RELEASE is still set, changes to the SOSCEN bit (OSCCON<1>) cannot take effect until the RELEASE bit is cleared.

In all other Deep Sleep wake-up cases, application firmware must clear the RELEASE bit in order to reconfigure the I/O pins.

## 10.4.5 DEEP SLEEP WDT

To enable the DSWDT in Deep Sleep mode, program the Configuration bit, DSWDTE (CW4<7>). The device WDT need not be enabled for the DSWDT to function. Entry into Deep Sleep modes automatically resets the DSWDT.

The DSWDT clock source is selected by the DSWDTOSC Configuration bit (CW4<5>). The postscaler options are programmed by the DSWDTPS<4:0> Configuration bits (CW4<4:0>). The minimum time-out period that can be achieved is 1 ms and the maximum is 25.7 days. For more information on the CW4 Configuration register and DSWDT configuration options, refer to [Section 30.0 “Special Features”](#).

### 10.4.5.1 Switching Clocks in Deep Sleep Mode

Both the RTCC and the DSWDT may run from either SOSC or the LPRC clock source. This allows both the RTCC and DSWDT to run without requiring both the LPRC and SOSC to be enabled together, reducing power consumption.

Running the RTCC from LPRC will result in a loss of accuracy in the RTCC of approximately 5 to 10%. If a more accurate RTCC is required, it must be run from the SOSC clock source. The RTCC clock source is selected with the RTCLK<1:0> bits (RTCPWC<11:10>).

Under certain circumstances, it is possible for the DSWDT clock source to be off when entering Deep Sleep mode. In this case, the clock source is turned on automatically (if DSWDT is enabled), without the need for software intervention. However, this can cause a delay in the start of the DSWDT counters. In order to avoid this delay when using SOSC as a clock source, the application can activate SOSC prior to entering Deep Sleep mode.

## 10.4.6 CHECKING AND CLEARING THE STATUS OF DEEP SLEEP

Upon entry into Deep Sleep mode, the status bit, DPSLP (RCON<10>), becomes set and must be cleared by the software.

On power-up, the software should read this status bit to determine if the Reset was due to an exit from Deep Sleep mode and clear the bit if it is set. Of the four possible combinations of DPSLP and POR bit states, the following three cases can be considered:

- Both the DPSLP and POR bits are cleared. In this case, the Reset was due to some event other than a Deep Sleep mode exit.
- The DPSLP bit is clear, but the POR bit is set; this is a normal Power-on Reset.
- Both the DPSLP and POR bits are set. This means that Deep Sleep mode was entered, the device was powered down and Deep Sleep mode was exited.

## 10.4.7 POWER-ON RESETS (PORs)

VDD voltage is monitored to produce PORs. Since exiting from Deep Sleep mode functionally looks like a POR, the technique described in [Section 10.4.6 “Checking and Clearing the Status of Deep Sleep”](#) should be used to distinguish between Deep Sleep and a true POR event. When a true POR occurs, the entire device, including all Deep Sleep logic (Deep Sleep registers, RTCC, DSWDT, etc.) is reset.

## 10.5 VBAT Mode

This mode represents the lowest power state that the microcontroller can achieve and still resume operation. VBAT mode is automatically triggered when the microcontroller's main power supply on VDD fails. When this happens, the microcontroller's on-chip power switch connects to a backup power source, such as a battery, supplied to the VBAT pin. This maintains a few key systems at an extremely low-power draw until VDD is restored.

The power supplied on VBAT only runs two systems: the RTCC and the Deep Sleep Semaphore registers (DSGPR0 and DSGPR1). To maintain these systems during a sudden loss of VDD, it is essential to connect a power source, other than VDD or AVDD, to the VBAT pin.

When the RTCC is enabled, it continues to operate with the same clock source (SOSC or LPRC) that was selected prior to entering VBAT mode. There is no provision to switch to a lower power clock source after the mode switch.

Since the loss of VDD is usually an unforeseen event, it is recommended that the contents of the Deep Sleep Semaphore registers be loaded with the data to be retained at an early point in code execution.

### 10.5.1 VBAT MODE WITH NO RTCC

By disabling RTCC operation during VBAT mode, power consumption is reduced to the lowest of all power-saving modes. In this mode, only the Deep Sleep Semaphore registers are maintained.

## 10.5.2 WAKE-UP FROM VBAT MODES

When VDD is restored to a device in VBAT mode, it automatically wakes. Wake-up occurs with a POR, after which, the device starts executing code from the Reset vector. All SFRs, except the Deep Sleep Semaphores, are reset to their POR values. If the RTCC was not configured to run during VBAT mode, it will remain disabled and RTCC will not run. Wake-up timing is similar to that for a normal POR.

To differentiate a wake-up from VBAT mode, from other POR states, check the VBAT status bit (RCON2<0>). If this bit is set while the device is starting to execute the code from the Reset vector, it indicates that there has been an exit from VBAT mode. The application must clear the VBAT bit to ensure that future VBAT wake-up events are captured.

If a POR occurs without a power source connected to the VBAT pin, the VBPOR bit (RCON2<1>) is set. If this bit is set on a Power-on Reset, it indicates that a battery needs to be connected to the VBAT pin.

In addition, if the VBAT power source falls below the level needed for Deep Sleep Semaphore operation while in VBAT mode (e.g., the battery has been drained), the VBPOR bit will be set. VBPOR is also set when the microcontroller is powered up the very first time, even if power is supplied to VBAT.

## 10.5.3 I/O PINS DURING VBAT MODES

All I/O pins switch to Input mode during VBAT mode. The only exceptions are the SOSCI and SOSCO pins, which maintain their states if the Secondary Oscillator is being used as the RTCC clock source. It is the user's responsibility to restore the I/O pins to their proper states using the TRISx and LATx bits once VDD has been restored.

## 10.5.4 SAVING CONTEXT DATA WITH THE DSGPRx REGISTERS

As with Deep Sleep mode (i.e., without the low-voltage/retention regulator), all SFRs are reset to their POR values after VDD has been restored. Only the Deep Sleep Semaphore registers are preserved. Applications which require critical data to be saved should save it in DSGPR0 and DSGPR1.

**Note:** If the VBAT mode is not used, it is recommended to connect the VBAT pin to VDD.

The POR should be enabled for the reliable operation of the VBAT.

- 2:** This bit indicates a VDD Power-on Reset. Setting the POR bit (RCON<0>) indicates a VCORE Power-on Reset.
- 3:** This bit is set when the device is originally powered up, even if power is present on VBAT.

## 10.6 Clock Frequency and Clock Switching

In Run and Idle modes, all PIC24FJ devices allow for a wide range of clock frequencies to be selected under application control. If the system clock configuration is not locked, users can choose low-power or high-precision oscillators by simply changing the NOSC<sub>x</sub> bits. The process of changing a system clock during operation, as well as limitations to the process, are discussed in more detail in [Section 9.0 “Oscillator Configuration”](#).

## 10.7 Doze Mode

Generally, changing clock speed and invoking one of the power-saving modes are the preferred strategies for reducing power consumption. There may be circumstances, however, where this is not practical. For example, it may be necessary for an application to maintain uninterrupted synchronous communication, even while it is doing nothing else. Reducing system clock speed may introduce communication errors, while using a power-saving mode may stop communications completely.

Doze mode is a simple and effective alternative method to reduce power consumption while the device is still executing code. In this mode, the system clock continues to operate from the same source and at the same speed. Peripheral modules continue to be clocked at the same speed, while the CPU clock speed is reduced. Synchronization between the two clock domains is maintained, allowing the peripherals to access the SFRs while the CPU executes code at a slower rate.

Doze mode is enabled by setting the DOZEN bit (CLKDIV<11>). The ratio between peripheral and core clock speed is determined by the DOZE<2:0> bits (CLKDIV<14:12>). There are eight possible configurations, from 1:1 to 1:128, with 1:1 being the default.

It is also possible to use Doze mode to selectively reduce power consumption in event driven applications. This allows clock-sensitive functions, such as synchronous communications, to continue without interruption while the CPU idles, waiting for something to invoke an interrupt routine. Enabling the automatic return to full-speed CPU operation on interrupts is enabled by setting the ROI bit (CLKDIV<15>). By default, interrupt events have no effect on Doze mode operation.

## 10.8 Selective Peripheral Module Control

Idle and Doze modes allow users to substantially reduce power consumption by slowing or stopping the CPU clock. Even so, peripheral modules still remain clocked, and thus, consume power. There may be cases where the application needs what these modes do not provide: the allocation of power resources to CPU processing, with minimal power consumption from the peripherals.

PIC24F devices address this requirement by allowing peripheral modules to be selectively disabled, reducing or eliminating their power consumption. This can be done with two control bits:

- The Peripheral Enable bit, generically named, “XXXEN”, located in the module’s main control SFR.
- The Peripheral Module Disable (PMD) bit, generically named, “XXXMD”, located in one of the PMD<sub>x</sub> Control registers (XXXMD bits are in the PMD1, PMD2, PMD3, PMD4, PMD6, PMD7, PMD8 registers).

Both bits have similar functions in enabling or disabling its associated module. Setting the PMD bit for a module disables all clock sources to that module, reducing its power consumption to an absolute minimum. In this state, the control and status registers associated with the peripheral will also be disabled, so writes to those registers will have no effect and read values will be invalid. Many peripheral modules have a corresponding PMD bit.

In contrast, disabling a module by clearing its XXXEN bit disables its functionality, but leaves its registers available to be read and written to. Power consumption is reduced, but not by as much as the use of the PMD bits. Most peripheral modules have an enable bit; exceptions include capture and RTCC.

To achieve more selective power savings, peripheral modules can also be selectively disabled when the device enters Idle mode. This is done through the control bit of the generic name format, “XXXSIDL”. By default, all modules that can operate during Idle mode will do so. Using the disable on Idle feature disables the module while in Idle mode, allowing further reduction of power consumption during Idle mode, enhancing power savings for extremely critical power applications.

---

**NOTES:**

## 11.0 I/O PORTS

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the "dsPIC33/PIC24 Family Reference Manual", "I/O Ports with Peripheral Pin Select (PPS)" (DS39711). The information in this data sheet supersedes the information in the FRM.

All of the device pins (except VDD, Vss, MCLR and OSC1/CLK1) are shared between the peripherals and the Parallel I/O ports. All I/O input ports feature Schmitt Trigger (ST) inputs for improved noise immunity.

### 11.1 Parallel I/O (PIO) Ports

A Parallel I/O port that shares a pin with a peripheral is, in general, subservient to the peripheral. The peripheral's output buffer data and control signals are provided to a pair of multiplexers. The multiplexers select whether the peripheral or the associated port has ownership of the output data and control signals of the I/O pin. The logic also prevents "loop through", in which a port's digital output can drive the input of a peripheral that shares the same pin. Figure 11-1 shows how ports are shared with other peripherals and the associated I/O pin to which they are connected.

When a peripheral is enabled and the peripheral is actively driving an associated pin, the use of the pin as a general purpose output pin is disabled. The I/O pin may be read, but the output driver for the parallel port bit will be disabled. If a peripheral is enabled, but the peripheral is not actively driving a pin, that pin may be driven by a port.

All port pins have three registers directly associated with their operation as digital I/Os and one register associated with their operation as analog inputs. The Data Direction register (TRIS) determines whether the pin is an input or an output. If the data direction bit is a '1', then the pin is an input. All port pins are defined as inputs after a Reset. Reads from the Output Latch register (LAT), read the latch; writes to the latch, write the latch. Reads from the port (PORT), read the port pins; writes to the port pins, write the latch.

Any bit, and its associated data and control registers that are not valid for a particular device, will be disabled. That means the corresponding LATx and TRISx registers, and the port pin, will read as zeros.

When a pin is shared with another peripheral or function that is defined as an input only, it is regarded as a dedicated port because there is no other competing source of inputs.

**FIGURE 11-1: BLOCK DIAGRAM OF A TYPICAL SHARED PORT STRUCTURE**

# PIC24FJ128GB204 FAMILY

---

## 11.1.1 I/O PORT WRITE/READ TIMING

One instruction cycle is required between a port direction change or port write operation and a read operation of the same port. Typically, this instruction would be a NOP.

## 11.1.2 OPEN-DRAIN CONFIGURATION

In addition to the PORTx, LATx and TRISx registers for data control, each port pin can also be individually configured for either a digital or open-drain output. This is controlled by the Open-Drain Control register, ODCx, associated with each port. Setting any of the bits configures the corresponding pin to act as an open-drain output.

The open-drain feature allows the generation of outputs higher than VDD (e.g., 5V), on any desired digital only pins, by using external pull-up resistors. The maximum open-drain voltage allowed is the same as the maximum VIH specification.

## 11.2 Configuring Analog Port Pins (ANSx)

The ANSx and TRISx registers control the operation of the pins with analog function. Each port pin with analog function is associated with one of the ANSx bits (see [Register 11-1](#) through [Register 11-3](#)), which decides if the pin function should be analog or digital. Refer to [Table 11-1](#) for detailed behavior of the pin for different ANSx and TRISx bit settings.

When reading the PORTx register, all pins configured as analog input channels will read as cleared (a low level).

### 11.2.1 ANALOG INPUT PINS AND VOLTAGE CONSIDERATIONS

The voltage tolerance of pins used as device inputs is dependent on the pin's input function. Most input pins are able to handle DC voltages of up to 5.5V, a level typical for digital logic circuits. However, several pins can only tolerate voltages up to VDD. Voltage excursions beyond VDD on these pins should always be avoided.

[Table 11-2](#) summarizes the different voltage tolerances. For more information, refer to [Section 33.0 "Electrical Characteristics"](#) for more details.

**TABLE 11-1: CONFIGURING ANALOG/DIGITAL FUNCTION OF AN I/O PIN**

Pin Function	ANSx Setting	TRISx Setting	Comments
Analog Input	1	1	It is recommended to keep ANSx = 1.
Analog Output	1	1	It is recommended to keep ANSx = 1.
Digital Input	0	1	Firmware must wait at least one instruction cycle after configuring a pin as a digital input before a valid input value can be read.
Digital Output	0	0	Make sure to disable the analog output function on the pin if any is present.

**TABLE 11-2: INPUT VOLTAGE LEVELS FOR PORT OR PIN TOLERATED DESCRIPTION INPUT**

Port or Pin	Tolerated Input	Description
PORTA<10:7,4> <sup>(1)</sup>	5.5V	Tolerates input levels above VDD; useful for most standard logic.
PORTB<11:10,8:4>		
PORTC<9:3> <sup>(1)</sup>		
PORTA<3:0>	VDD	Only VDD input levels are tolerated.
PORTB<15:13,9,3:0>		
PORTC<2:0> <sup>(1)</sup>		

**Note 1:** Not all of these pins are implemented in 28-pin devices. Refer to [Section 1.0 "Device Overview"](#) for a complete description of port pin implementation.

## 11.3 Input Change Notification (ICN)

The Input Change Notification function of the I/O ports allows the PIC24FJ128GB204 family of devices to generate interrupt requests to the processor in response to a Change-of-State (COS) on selected input pins. This feature is capable of detecting input Change-of-States, even in Sleep mode, when the clocks are disabled. Depending on the device pin count, there are up to 82 external inputs that may be selected (enabled) for generating an interrupt request on a Change-of-State.

Registers, CNEN1 through CNEN3, contain the interrupt enable control bits for each of the CN input pins. Setting any of these bits enables a CN interrupt for the corresponding pins.

Each CN pin has both a weak pull-up and a weak pull-down connected to it. The pull-ups act as a current source that is connected to the pin, while the pull-downs act as a current sink that is connected to the pin. These eliminate the need for external resistors when push button or keypad devices are connected. The pull-ups and pull-downs are separately enabled using the CNPU1 through CNPU3 registers (for pull-ups), and the CNPD1 through CNPD3 registers (for pull-downs). Each CN pin has individual control bits for its pull-up and pull-down. Setting a control bit enables the weak pull-up or pull-down for the corresponding pin.

When the internal pull-up is selected, the pin pulls up to VDD – 1.1V (typical). When the internal pull-down is selected, the pin pulls down to Vss.

**Note:** Pull-ups on Input Change Notification pins should always be disabled whenever the port pin is configured as a digital output.

### EXAMPLE 11-1: PORT READ/WRITE IN ASSEMBLY

```
MOV 0xFF00, W0 ; Configure PORTB<15:8> as inputs
MOV W0, TRISB ; and PORTB<7:0> as outputs
NOP ; Delay 1 cycle
BTSS PORTB, #13 ; Next Instruction
```

### EXAMPLE 11-2: PORT READ/WRITE IN ‘C’

```
TRISB = 0xFF00; // Configure PORTB<15:8> as inputs and PORTB<7:0> as outputs
Nop(); // Delay 1 cycle
IF (PORTBbits.RB13){ }; // Next Instruction
```

## 11.4 Peripheral Pin Select (PPS)

A major challenge in general purpose devices is providing the largest possible set of peripheral features while minimizing the conflict of features on I/O pins. In an application that needs to use more than one peripheral multiplexed on a single pin, inconvenient work arounds in application code, or a complete redesign, may be the only option.

The Peripheral Pin Select (PPS) feature provides an alternative to these choices by enabling the user's peripheral set selection and its placement on a wide range of I/O pins. By increasing the pinout options available on a particular device, users can better tailor the microcontroller to their entire application, rather than trimming the application to fit the device.

The Peripheral Pin Select feature operates over a fixed subset of digital I/O pins. Users may independently map the input and/or output of any one of many digital peripherals to any one of these I/O pins. PPS is performed in software and generally does not require the device to be reprogrammed. Hardware safeguards are included that prevent accidental or spurious changes to the peripheral mapping once it has been established.

### 11.4.1 AVAILABLE PINS

The PPS feature is used with a range of up to 44 pins, depending on the particular device and its pin count. Pins that support the Peripheral Pin Select feature include the designation, "RPn" or "RPln", in their full pin designation, where "n" is the remappable pin number. "RP" is used to designate pins that support both remappable input and output functions, while "RPI" indicates pins that support remappable input functions only.

PIC24FJ128GB204 family devices support a larger number of remappable input only pins than remappable input/output pins. In this device family, there are up to 25 remappable input/output pins, depending on the pin count of the particular device selected. These pins are numbered, RP0 through RP25.

See [Table 1-3](#) for a summary of pinout options in each package offering.

### 11.4.2 AVAILABLE PERIPHERALS

The peripherals managed by the PPS are all digital only peripherals. These include general serial communications (UART and SPI), general purpose timer clock inputs, timer related peripherals (input capture and output compare) and external interrupt inputs. Also included are the outputs of the comparator module, since these are discrete digital signals.

PPS is not available for these peripherals:

- I<sup>2</sup>C™ (input and output)
- USB (all module inputs and outputs)
- Change Notification Inputs
- RTCC Alarm Output(s)
- EPMP Signals (input and output)
- Analog (inputs and outputs)
- INT0

A key difference between pin select and non-pin select peripherals is that pin select peripherals are not associated with a default I/O pin. The peripheral must always be assigned to a specific I/O pin before it can be used. In contrast, non-pin select peripherals are always available on a default pin, assuming that the peripheral is active and not conflicting with another peripheral.

#### 11.4.2.1 Peripheral Pin Select Function Priority

Pin-selectable peripheral outputs (e.g., OC, UART transmit) will take priority over general purpose digital functions on a pin, such as EPMP and port I/O. Specialized digital outputs (e.g., USB on USB-enabled devices) will take priority over PPS outputs on the same pin. The pin diagrams list peripheral outputs in the order of priority. Refer to them for priority concerns on a particular pin.

Unlike PIC24F devices with fixed peripherals, pin-selectable peripheral inputs will never take ownership of a pin. The pin's output buffer will be controlled by the TRISx setting or by a fixed peripheral on the pin. If the pin is configured in Digital mode, then the PPS input will operate correctly. If an analog function is enabled on the pin, the PPS input will be disabled.

#### 11.4.3 CONTROLLING PERIPHERAL PIN SELECT

PPS features are controlled through two sets of Special Function Registers (SFRs): one to map peripheral inputs and one to map outputs. Because they are separately controlled, a particular peripheral's input and output (if the peripheral has both) can be placed on any selectable function pin without constraint.

The association of a peripheral to a peripheral-selectable pin is handled in two different ways, depending on if an input or an output is being mapped.

### 11.4.3.1 Input Mapping

The inputs of the Peripheral Pin Select options are mapped on the basis of the peripheral; that is, a control register associated with a peripheral dictates the pin it will be mapped to. The RPINRx registers are used to configure peripheral input mapping (see [Register 11-4](#) through [Register 11-22](#)).

Each register contains two sets of 6-bit fields, with each set associated with one of the pin-selectable peripherals. Programming a given peripheral's bit field with an appropriate 6-bit value maps the RPn/RPin pin with that value to that peripheral. For any given device, the valid range of values for any of the bit fields corresponds to the maximum number of Peripheral Pin Selections supported by the device.

**TABLE 11-3: SELECTABLE INPUT SOURCES (MAPS INPUT TO FUNCTION)<sup>(1)</sup>**

---

## 11.4.3.2 Output Mapping

In contrast to inputs, the outputs of the Peripheral Pin Select options are mapped on the basis of the pin. In this case, a control register associated with a particular pin dictates the peripheral output to be mapped. The RPORx registers are used to control output mapping. Each register contains two 6-bit fields, with each field being associated with one RPn pin (see [Register 11-23](#) through [Register 11-35](#)). The value of the bit field

corresponds to one of the peripherals and that peripheral's output is mapped to the pin (see [Table 11-4](#)).

Because of the mapping technique, the list of peripherals for output mapping also includes a null value of '000000'. This permits any given pin to remain disconnected from the output of any of the pin-selectable peripherals.

**TABLE 11-4: SELECTABLE OUTPUT SOURCES (MAPS FUNCTION TO OUTPUT)**

Output Function Number <sup>(1)</sup>	Function	Output Name
0	NULL <sup>(2)</sup>	Null
1	C1OUT	Comparator 1 Output
2	C2OUT	Comparator 2 Output
3	U1TX	UART1 Transmit
4	U1RTS <sup>(3)</sup>	UART1 Request-to-Send
5	U2TX	UART2 Transmit
6	U2RTS <sup>(3)</sup>	UART2 Request-to-Send
7	SDO1	SPI1 Data Output
8	SCK1OUT	SPI1 Clock Output
9	SS1OUT	SPI1 Slave Select Output
10	SDO2	SPI2 Data Output
11	SCK2OUT	SPI2 Clock Output
12	SS2OUT	SPI2 Slave Select Output
13	OC1	Output Compare 1
14	OC2	Output Compare 2
15	OC3	Output Compare 3
16	OC4	Output Compare 4
17	OC5	Output Compare 5
18	OC6	Output Compare 6
19	U3TX	UART3 Transmit
20	U3RTS	UART3 Request-to-Send
21	U4TX	UART4 Transmit
22	U4RTS <sup>(3)</sup>	UART4 Request-to-Send
23	SDO3	SPI3 Data Output
24	SCK3OUT	SPI3 Clock Output
25	SS3OUT	SPI3 Slave Select Output
26	C3OUT	Comparator 3 Output
27	MDOUT	DSM Modulator Output

**Note 1:** Setting the RPORx register with the listed value assigns that output function to the associated RPn pin.

**2:** The NULL function is assigned to all RPn outputs at device Reset and disables the RPn output function.

**3:** IrDA® BCLK functionality uses this output.

### 11.4.3.3 Mapping Limitations

The control schema of the Peripheral Pin Select is extremely flexible. Other than systematic blocks that prevent signal contention, caused by two physical pins being configured as the same functional input or two functional outputs configured as the same pin, there are no hardware enforced lockouts. The flexibility extends to the point of allowing a single input to drive multiple peripherals or a single functional output to drive multiple output pins.

### 11.4.3.4 Mapping Exceptions for PIC24FJ128GB204 Family Devices

Although the PPS registers theoretically allow for up to 24 remappable I/O pins, not all of these are implemented in all devices. For PIC24FJ128GB204 family devices, the maximum number of remappable pins available is 24, which includes one input only pin. The differences in available remappable pins are summarized in [Table 11-5](#).

When developing applications that use remappable pins, users should also keep these things in mind:

- For the RPINRx registers, bit combinations corresponding to an unimplemented pin for a particular device are treated as invalid; the corresponding module will not have an input mapped to it.
- For RPORx registers, the bit fields corresponding to an unimplemented pin will also be unimplemented; writing to these fields will have no effect.

### 11.4.4 CONTROLLING CONFIGURATION CHANGES

Because peripheral remapping can be changed during run time, some restrictions on peripheral remapping are needed to prevent accidental configuration changes. PIC24F devices include three features to prevent alterations to the peripheral map:

- Control register lock sequence
- Continuous state monitoring
- Configuration bit remapping lock

### 11.4.4.1 Control Register Lock

Under normal operation, writes to the RPINRx and RPORx registers are not allowed. Attempted writes will appear to execute normally, but the contents of the registers will remain unchanged. To change these registers, they must be unlocked in hardware. The register lock is controlled by the IOLOCK bit (OSCCON<6>). Setting IOLOCK prevents writes to the control registers; clearing IOLOCK allows writes.

To set or clear IOLOCK, a specific command sequence must be executed:

1. Write 46h to OSCCON<7:0>.
2. Write 57h to OSCCON<7:0>.
3. Clear (or set) IOLOCK as a single operation.

Unlike the similar sequence with the oscillator's LOCK bit, IOLOCK remains in one state until changed. This allows all of the Peripheral Pin Selects to be configured with a single unlock sequence, followed by an update to all control registers, then locked with a second lock sequence.

### 11.4.4.2 Continuous State Monitoring

In addition to being protected from direct writes, the contents of the RPINRx and RPORx registers are constantly monitored in hardware by shadow registers. If an unexpected change in any of the registers occurs (such as cell disturbances caused by ESD or other external events), a Configuration Mismatch Reset will be triggered.

### 11.4.4.3 Configuration Bit Pin Select Lock

As an additional level of safety, the device can be configured to prevent more than one write session to the RPINRx and RPORx registers. The IOL1WAY (CW4<15>) Configuration bit blocks the IOLOCK bit from being cleared after it has been set once. If IOLOCK remains set, the register unlock procedure will not execute and the Peripheral Pin Select Control registers cannot be written to. The only way to clear the bit and re-enable peripheral remapping is to perform a device Reset.

In the default (unprogrammed) state, IOL1WAY is set, restricting users to one write session. Programming IOL1WAY allows users unlimited access (with the proper use of the unlock sequence) to the Peripheral Pin Select registers.

**TABLE 11-5: REMAPPABLE PIN EXCEPTIONS FOR PIC24FJ128GB204 FAMILY DEVICES**

Device	RPn Pins (I/O)		RPI <sub>n</sub> Pins	
	Total	Unimplemented	Total	Unimplemented
PIC24FJXXXGB202	14	RP4, RP12	1	—
PIC24FJXXXGB204	24	RP4, RP12	1	—

# PIC24FJ128GB204 FAMILY

## 11.4.5 CONSIDERATIONS FOR PERIPHERAL PIN SELECTION

The ability to control Peripheral Pin Selection introduces several considerations into application design that could be overlooked. This is particularly true for several common peripherals that are available only as remappable peripherals.

The main consideration is that the Peripheral Pin Selects are not available on default pins in the device's default (Reset) state. Since all RPINRx registers reset to '111111' and all RPORx registers reset to '000000', all Peripheral Pin Select inputs are tied to Vss and all Peripheral Pin Select outputs are disconnected.

This situation requires the user to initialize the device with the proper peripheral configuration before any other application code is executed. Since the IOLOCK bit resets in the unlocked state, it is not necessary to execute the unlock sequence after the device has come out of Reset. For application safety, however, it is best to set IOLOCK and lock the configuration after writing to the control registers.

Because the unlock sequence is timing-critical, it must be executed as an assembly language routine in the same manner as changes to the oscillator configuration. If the bulk of the application is written in 'C', or another high-level language, the unlock sequence should be performed by writing in-line assembly.

Choosing the configuration requires the review of all Peripheral Pin Selects and their pin assignments, especially those that will not be used in the application. In all cases, unused pin-selectable peripherals should be disabled completely. Unused peripherals should have their inputs assigned to an unused RPn/RPIn pin function. I/O pins with unused RPn functions should be configured with the null peripheral output.

The assignment of a peripheral to a particular pin does not automatically perform any other configuration of the pin's I/O circuitry. In theory, this means adding a pin-selectable output to a pin may mean inadvertently driving an existing peripheral input when the output is driven. Users must be familiar with the behavior of other fixed peripherals that share a remappable pin and know when to enable or disable them. To be safe, fixed digital peripherals that share the same pin should be disabled when not in use.

Along these lines, configuring a remappable pin for a specific peripheral does not automatically turn that feature on. The peripheral must be specifically configured for operation and enabled as if it were tied to a fixed pin. Where this happens in the application code (immediately following a device Reset and peripheral configuration or inside the main application routine) depends on the peripheral and its use in the application.

A final consideration is that Peripheral Pin Select functions neither override analog inputs nor reconfigure pins with analog functions for digital I/O. If a pin is configured as an analog input on device Reset, it must be explicitly reconfigured as a digital I/O when used with a Peripheral Pin Select.

**Example 11-3** shows a configuration for bidirectional communication with flow control using UART1. The following input and output functions are used:

- Input Functions: U1RX,  $\overline{U1CTS}$
- Output Functions: U1TX,  $\overline{U1RTS}$

## EXAMPLE 11-3: CONFIGURING UART1 INPUT AND OUTPUT FUNCTIONS

```
// Unlock Registers
asm volatile ("MOV #OSCCON, w1\n"
              "MOV #0x46, w2\n"
              "MOV #0x57, w3\n"
              "MOV.b w2, [w1]\n"
              "MOV.b w3, [w1]\n"
              "BCLR OSCCON, #6");;

// or use C30 built-in macro:
// __builtin_write_OSCCONL(OSCCON & 0xbf);

// Configure Input Functions (Table 11-3)
// Assign U1RX To Pin RP0
RPINR18bits.U1RXR = 0;

// Assign U1CTS To Pin RP1
RPINR18bits.U1CTSR = 1;

// Configure Output Functions (Table 11-4)
// Assign U1TX To Pin RP2
RPOR1bits.RP2R = 3;

// Assign U1RTS To Pin RP3
RPOR1bits.RP3R = 4;

// Lock Registers
asm volatile ("MOV #OSCCON, w1\n"
              "MOV #0x46, w2\n"
              "MOV #0x57, w3\n"
              "MOV.b w2, [w1]\n"
              "MOV.b w3, [w1]\n"
              "BSET OSCCON, #6");;

// or use C30 built-in macro:
// __builtin_write_OSCCONL(OSCCON | 0x40);
```

# PIC24FJ128GB204 FAMILY

## 11.4.6 PERIPHERAL PIN SELECT REGISTERS

The PIC24FJ128GB204 family of devices implements a total of 32 registers for remappable peripheral configuration:

- Input Remappable Peripheral Registers (19)
- Output Remappable Peripheral Registers (13)

**Note:** Input and Output register values can only be changed if IOLOCK (OSCCON<6>) = 0. See [Section 11.4.4.1 “Control Register Lock”](#) for a specific command sequence.

**NOTES:**

## 12.0 TIMER1

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Timers” (DS39704). The information in this data sheet supersedes the information in the FRM.

The Timer1 module is a 16-bit timer, which can serve as the time counter for the Real-Time Clock (RTC) or operate as a free-running, interval timer/counter. Timer1 can operate in three modes:

- 16-Bit Timer
- 16-Bit Synchronous Counter
- 16-Bit Asynchronous Counter

Timer1 also supports these features:

- Timer Gate Operation
- Selectable Prescaler Settings
- Timer Operation during CPU Idle and Sleep modes
- Interrupt on 16-Bit Period Register Match or Falling Edge of External Gate Signal

**FIGURE 12-1: 16-BIT TIMER1 MODULE BLOCK DIAGRAM**

Figure 12-1 shows a block diagram of the 16-bit timer module.

To configure Timer1 for operation:

1. Set the TON bit (= 1).
2. Select the timer prescaler ratio using the TCKPS<1:0> bits.
3. Set the Clock and Gating modes using the TCS, TECS<1:0> and TGATE bits.
4. Set or clear the TSYNC bit to configure synchronous or asynchronous operation.
5. Load the timer period value into the PR1 register.
6. If interrupts are required, set the Timer1 Interrupt Enable bit, T1IE. Use the Timer1 Interrupt Priority bits, T1IP<2:0>, to set the interrupt priority.

**NOTES:**

## 13.0 TIMER2/3 AND TIMER4/5

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Timers” (DS39704). The information in this data sheet supersedes the information in the FRM.

The Timer2/3 and Timer4/5 modules are 32-bit timers, which can also be configured as four independent, 16-bit timers with selectable operating modes.

As 32-bit timers, Timer2/3 and Timer4/5 can each operate in three modes:

- Two Independent 16-Bit Timers with all 16-Bit Operating modes (except Asynchronous Counter mode)
- Single 32-Bit Timer
- Single 32-Bit Synchronous Counter

They also support these features:

- Timer Gate Operation
- Selectable Prescaler Settings
- Timer Operation during Idle and Sleep modes
- Interrupt on a 32-Bit Period Register Match
- A/D Event Trigger (only on Timer2/3 in 32-bit mode and Timer3 in 16-bit mode)

Individually, all four of the 16-bit timers can function as synchronous timers or counters. They also offer the features listed above, except for the A/D Event Trigger. This trigger is implemented only on Timer2/3 in 32-bit mode and Timer3 in 16-bit mode. The operating modes and enabled features are determined by setting the appropriate bit(s) in the T2CON, T3CON, T4CON and T5CON registers. T2CON and T4CON are shown in generic form in [Register 13-1](#); T3CON and T5CON are shown in [Register 13-2](#).

For 32-bit timer/counter operation, Timer2 and Timer4 are the least significant word; Timer3 and Timer5 are the most significant word of the 32-bit timers.

**Note:** For 32-bit operation, T3CON and T5CON control bits are ignored. Only T2CON and T4CON control bits are used for setup and control. Timer2 and Timer4 clock and gate inputs are utilized for the 32-bit timer modules, but an interrupt is generated with the Timer3 or Timer5 interrupt flags.

To configure Timer2/3 or Timer4/5 for 32-bit operation:

1. Set the T32 or T45 bit (T2CON<3> or T4CON<3> = 1).
2. Select the prescaler ratio for Timer2 or Timer4 using the TCKPS<1:0> bits.
3. Set the Clock and Gating modes using the TCS and TGATE bits. If TCS is set to an external clock, RPINRx (TxCK) must be configured to an available RPn/RPI<sub>n</sub> pin. For more information, see [Section 11.4 “Peripheral Pin Select \(PPS\)”](#).
4. Load the timer period value. PR3 (or PR5) will contain the most significant word (msw) of the value, while PR2 (or PR4) contains the least significant word (lsw).
5. If interrupts are required, set the Timer3/5 Interrupt Enable bit, T3IE or T5IE. Use the Timer3/5 Interrupt Priority bits, T3IP<2:0> or T5IP<2:0>, to set the interrupt priority. Note that while Timer2 or Timer4 controls the timer, the interrupt appears as a Timer3 or Timer5 interrupt.
6. Set the TON bit (= 1).

The timer value, at any point, is stored in the register pair, TMR<3:2> (or TMR<5:4>). TMR3 (TMR5) always contains the most significant word of the count, while TMR2 (TMR4) contains the least significant word.

To configure any of the timers for individual 16-bit operation:

1. Clear the T32 bit corresponding to that timer (T2CON<3> for Timer2 and Timer3 or T4CON<3> for Timer4 and Timer5).
2. Select the timer prescaler ratio using the TCKPS<1:0> bits.
3. Set the Clock and Gating modes using the TCS and TGATE bits. See [Section 11.4 “Peripheral Pin Select \(PPS\)”](#) for more information.
4. Load the timer period value into the PRx register.
5. If interrupts are required, set the Timerx Interrupt Enable bit, TxIE. Use the Timerx Interrupt Priority bits, TxIP<2:0>, to set the interrupt priority.
6. Set the TON (TxCON<15> = 1) bit.

bit 3-2	<b>Unimplemented:</b> Read as '0'
bit 1	<b>TCS:</b> Timery Clock Source Select bit <sup>(2,3)</sup> 1 = External clock from pin, TyCK (on the rising edge) 0 = Internal clock (Fosc/2)
bit 0	<b>Unimplemented:</b> Read as '0'

- Note 1:** Changing the value of TyCON while the timer is running (TON = 1) causes the timer prescale counter to reset and is not recommended.
- 2:** When 32-bit operation is enabled (T2CON<3> or T4CON<3> = 1), these bits have no effect on Timery operation; all timer functions are set through T2CON and T4CON.
- 3:** If TCS = 1 and TECS<1:0> = x1, the selected external timer input (TyCK) must be configured to an available RPn/RPIn pin. For more information, see [Section 11.4 “Peripheral Pin Select \(PPS\)”](#).

## 14.0 INPUT CAPTURE WITH DEDICATED TIMERS

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Input Capture with Dedicated Timer” (DS39722). The information in this data sheet supersedes the information in the FRM.

Devices in the PIC24FJ128GB204 family contain six independent input capture modules. Each of the modules offers a wide range of configuration and operating options for capturing external pulse events and generating interrupts.

Key features of the input capture module include:

- Hardware-configurable for 32-bit operation in all modes by cascading two adjacent modules
- Synchronous and Trigger modes of output compare operation, with up to 30 user-selectable sync/trigger sources available
- A 4-level FIFO buffer for capturing and holding timer values for several events
- Configurable interrupt generation
- Up to 6 clock sources available for each module, driving a separate, internal 16-bit counter

The module is controlled through two registers: ICxCON1 ([Register 14-1](#)) and ICxCON2 ([Register 14-2](#)). A general block diagram of the module is shown in [Figure 14-1](#).

**FIGURE 14-1: INPUT CAPTURE x BLOCK DIAGRAM**

## 14.1 General Operating Modes

### 14.1.1 SYNCHRONOUS AND TRIGGER MODES

When the input capture module operates in a Free-Running mode, the internal 16-bit counter, ICxTMR, counts up continuously, wrapping around from FFFFh to 0000h on each overflow. Its period is synchronized to the selected external clock source. When a capture event occurs, the current 16-bit value of the internal counter is written to the FIFO buffer.

In Synchronous mode, the module begins capturing events on the ICx pin as soon as its selected clock source is enabled. Whenever an event occurs on the selected sync source, the internal counter is reset. In Trigger mode, the module waits for a sync event from another internal module to occur before allowing the internal counter to run.

Standard, free-running operation is selected by setting the SYNCSELx bits (ICxCON2<4:0>) to ‘00000’ and clearing the ICTRIG bit (ICxCON2<7>). Synchronous and Trigger modes are selected any time the SYNCSELx bits are set to any value except ‘00000’. The ICTRIG bit selects either Synchronous or Trigger mode; setting the bit selects Trigger mode operation. In both modes, the SYNCSELx bits determine the sync/trigger source.

When the SYNCSELx bits are set to ‘00000’ and ICTRIG is set, the module operates in Software Trigger mode. In this case, capture operations are started by manually setting the TRIGSTAT bit (ICxCON2<6>).

# PIC24FJ128GB204 FAMILY

---

## 14.1.2 CASCADED (32-BIT) MODE

By default, each module operates independently with its own 16-bit timer. To increase resolution, adjacent even and odd modules can be configured to function as a single 32-bit module. (For example, Modules 1 and 2 are paired, as are Modules 3 and 4, and so on.) The odd numbered module, Input Capture x (ICx), provides the Least Significant 16 bits of the 32-bit register pairs and the even numbered module, Input Capture y (ICy), provides the Most Significant 16 bits. Wrap arounds of the ICx registers cause an increment of their corresponding ICy registers.

Cascaded operation is configured in hardware by setting the IC32 bits (ICxCON2<8>) for both modules.

## 14.2 Capture Operations

The input capture module can be configured to capture timer values and generate interrupts on rising edges on ICx or all transitions on ICx. Captures can be configured to occur on all rising edges or just some (every 4<sup>th</sup> or 16<sup>th</sup>). Interrupts can be independently configured to generate on each event or a subset of events.

To set up the module for capture operations:

1. Configure the ICx input for one of the available Peripheral Pin Select pins.
2. If Synchronous mode is to be used, disable the sync source before proceeding.
3. Make sure that any previous data has been removed from the FIFO by reading ICxBUF until the ICBNE bit (ICxCON1<3>) is cleared.
4. Set the SYNCSELx bits (ICxCON2<4:0>) to the desired sync/trigger source.
5. Set the ICTSELx bits (ICxCON1<12:10>) for the desired clock source.
6. Set the ICIx bits (ICxCON1<6:5>) to the desired interrupt frequency
7. Select Synchronous or Trigger mode operation:
  - a) Check that the SYNCSELx bits are not set to '00000'.
  - b) For Synchronous mode, clear the ICTRIG bit (ICxCON2<7>).
  - c) For Trigger mode, set ICTRIG and clear the TRIGSTAT bit (ICxCON2<6>).
8. Set the ICMx bits (ICxCON1<2:0>) to the desired operational mode.
9. Enable the selected sync/trigger source.

For 32-bit cascaded operations, the setup procedure is slightly different:

1. Set the IC32 bits for both modules (ICyCON2<8> and ICxCON2<8>), enabling the even numbered module first. This ensures that the modules will start functioning in unison.
2. Set the ICTSELx and SYNCSELx bits for both modules to select the same sync/trigger and time base source. Set the even module first, then the odd module. Both modules must use the same ICTSELx and SYNCSELx bit settings.
3. Clear the ICTRIG bit of the even module (ICyCON2<7>). This forces the module to run in Synchronous mode with the odd module, regardless of its trigger setting.
4. Use the odd module's ICIx bits (ICxCON1<6:5>) to set the desired interrupt frequency.
5. Use the ICTRIG bit of the odd module (ICxCON2<7>) to configure Trigger or Synchronous mode operation.

**Note:** For Synchronous mode operation, enable the sync source as the last step. Both input capture modules are held in Reset until the sync source is enabled.

6. Use the ICMx bits of the odd module (ICxCON1<2:0>) to set the desired Capture mode.

The module is ready to capture events when the time base and the sync/trigger source are enabled. When the ICBNE bit (ICxCON1<3>) becomes set, at least one capture value is available in the FIFO. Read input capture values from the FIFO until the ICBNE clears to '0'.

For 32-bit operation, read both the ICxBUF and ICyBUF for the full 32-bit timer value (ICxBUF for the lsw, ICyBUF for the msw). At least one capture value is available in the FIFO buffer when the odd module's ICBNE bit (ICxCON1<3>) becomes set. Continue to read the buffer registers until ICBNE is cleared (performed automatically by hardware).

**NOTES:**

## 15.0 OUTPUT COMPARE WITH DEDICATED TIMERS

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “*dsPIC33/PIC24 Family Reference Manual*”, “**Output Compare with Dedicated Timer**” (DS70005159). The information in this data sheet supersedes the information in the FRM.

Devices in the PIC24FJ128GB204 family all feature six independent output compare modules. Each of these modules offers a wide range of configuration and operating options for generating pulse trains on internal device events, and can produce Pulse-Width Modulated (PWM) waveforms for driving power applications.

Key features of the output compare module include:

- Hardware-configurable for 32-bit operation in all modes by cascading two adjacent modules
- Synchronous and Trigger modes of output compare operation, with up to 31 user-selectable trigger/sync sources available
- Two separate Period registers (a main register, OCxR, and a secondary register, OCxRS) for greater flexibility in generating pulses of varying widths
- Configurable for single pulse or continuous pulse generation on an output event, or continuous PWM waveform generation
- Up to 6 clock sources available for each module, driving a separate internal 16-bit counter

## 15.1 General Operating Modes

### 15.1.1 SYNCHRONOUS AND TRIGGER MODES

When the output compare module operates in a Free-Running mode, the internal 16-bit counter, OCxTMR, runs counts up continuously, wrapping around from 0xFFFF to 0x0000 on each overflow. Its period is synchronized to the selected external clock source. Compare or PWM events are generated each time a match between the internal counter and one of the Period registers occurs.

In Synchronous mode, the module begins performing its compare or PWM operation as soon as its selected clock source is enabled. Whenever an event occurs on the selected sync source, the module's internal counter is reset. In Trigger mode, the module waits for a sync event from another internal module to occur before allowing the counter to run.

Free-Running mode is selected by default or any time that the SYNCSELx bits (OCxCON2<4:0>) are set to ‘00000’. Synchronous or Trigger modes are selected any time the SYNCSELx bits are set to any value except ‘00000’. The OCTRIG bit (OCxCON2<7>) selects either Synchronous or Trigger mode; setting the bit selects Trigger mode operation. In both modes, the SYNCSELx bits determine the sync/trigger source.

### 15.1.2 CASCADED (32-BIT) MODE

By default, each module operates independently with its own set of 16-bit Timer and Duty Cycle registers. To increase resolution, adjacent even and odd modules can be configured to function as a single 32-bit module. (For example, Modules 1 and 2 are paired, as are Modules 3 and 4, and so on.) The odd numbered module, Output Compare x (OCx), provides the Least Significant 16 bits of the 32-bit register pairs and the even numbered module, Output Compare y (OCy), provides the Most Significant 16 bits. Wrap arounds of the OCx registers cause an increment of their corresponding OCy registers.

Cascaded operation is configured in hardware by setting the OC32 bit (OCxCON2<8>) for both modules. For more information on cascading, refer to the “*dsPIC33/PIC24 Family Reference Manual*”, “**Output Compare with Dedicated Timer**” (DS70005159).

# PIC24FJ128GB204 FAMILY

**FIGURE 15-1: OUTPUT COMPARE x BLOCK DIAGRAM (16-BIT MODE)**

## 15.2 Compare Operations

In Compare mode ([Figure 15-1](#)), the output compare module can be configured for single-shot or continuous pulse generation. It can also repeatedly toggle an output pin on each timer event.

To set up the module for compare operations:

1. Configure the OCx output for one of the available Peripheral Pin Select pins.
2. Calculate the required values for the OCxR and (for Double Compare modes) OCxRS Duty Cycle registers:
  - a) Determine the instruction clock cycle time. Take into account the frequency of the external clock to the timer source (if one is used) and the timer prescaler settings.
  - b) Calculate the time to the rising edge of the output pulse relative to the timer start value (0000h).
  - c) Calculate the time to the falling edge of the pulse based on the desired pulse width and the time to the rising edge of the pulse.

3. Write the rising edge value to OCxR and the falling edge value to OCxRS.
4. Set the Timer Period register, PRy, to a value equal to or greater than the value in OCxRS.
5. Set the OCM<2:0> bits for the appropriate compare operation ('0xx').
6. For Trigger mode operations, set OCTRIG to enable Trigger mode. Set or clear TRIGMODE to configure trigger operation and TRIGSTAT to select a hardware or software trigger. For Synchronous mode, clear OCTRIG.
7. Set the SYNCSEL<4:0> bits to configure the trigger or synchronization source. If free-running timer operation is required, set the SYNCSELx bits to '00000' (no sync/trigger source).
8. Select the time base source with the OCTSEL<2:0> bits. If necessary, set the TON bit for the selected timer, which enables the compare time base to count. Synchronous mode operation starts as soon as the time base is enabled; Trigger mode operation starts after a trigger source event occurs.

For 32-bit cascaded operation, these steps are also necessary:

1. Set the OC32 bits for both registers (OCyCON2<8>) and (OCxCON2<8>). Enable the even numbered module first to ensure the modules will start functioning in unison.
2. Clear the OCTRIG bit of the even module (OCyCON2<7>), so the module will run in Synchronous mode.
3. Configure the desired output and Fault settings for OCy.
4. Force the output pin for OCx to the output state by clearing the OCTRIS bit.
5. If Trigger mode operation is required, configure the trigger options in OCx by using the OCTRIG (OCxCON2<7>), TRIGMODE (OCxCON1<3>) and SYNCSELx (OCxCON2<4:0>) bits.
6. Configure the desired Compare or PWM mode of operation (OCM<2:0>) for OCy first, then for OCx.

Depending on the output mode selected, the module holds the OCx pin in its default state and forces a transition to the opposite state when OCxR matches the timer. In Double Compare modes, OCx is forced back to its default state when a match with OCxRS occurs. The OCxIF interrupt flag is set after an OCxR match in Single Compare modes and after each OCxRS match in Double Compare modes.

Single-shot pulse events only occur once, but may be repeated by simply rewriting the value of the OCxCON1 register. Continuous pulse events continue indefinitely until terminated.

## 15.3 Pulse-Width Modulation (PWM) Mode

In PWM mode, the output compare module can be configured for edge-aligned or center-aligned pulse waveform generation. All PWM operations are double-buffered (buffer registers are internal to the module and are not mapped into SFR space).

To configure the output compare module for PWM operation:

1. Configure the OCx output for one of the available Peripheral Pin Select pins.
2. Calculate the desired duty cycles and load them into the OCxR register.
3. Calculate the desired period and load it into the OCxRS register.
4. Select the current OCx as the synchronization source by writing '0x1F' to the SYNCSEL<4:0> bits (OCxCON2<4:0>) and '0' to the OCTRIG bit (OCxCON2<7>).
5. Select a clock source by writing to the OCTSEL<2:0> bits (OCxCON1<12:10>).
6. Enable interrupts, if required, for the timer and output compare modules. The output compare interrupt is required for PWM Fault pin utilization.
7. Select the desired PWM mode in the OCM<2:0> bits (OCxCON1<2:0>).
8. Appropriate Fault inputs may be enabled by using the ENFLT<2:0> bits as described in [Register 15-1](#).
9. If a timer is selected as a clock source, set the selected timer prescale value. The selected timer's prescaler output is used as the clock input for the OCx timer and not the selected timer output.

**Note:** This peripheral contains input and output functions that may need to be configured by the Peripheral Pin Select. For more information, see [Section 11.4 “Peripheral Pin Select \(PPS\)”](#).

# PIC24FJ128GB204 FAMILY

**FIGURE 15-2: OUTPUT COMPARE x BLOCK DIAGRAM (DOUBLE-BUFFERED, 16-BIT PWM MODE)**

## 15.3.1 PWM PERIOD

The PWM period is specified by writing to PRy, the Timer Period register. The PWM period can be calculated using [Equation 15-1](#).

### EQUATION 15-1: CALCULATING THE PWM PERIOD<sup>(1)</sup>

$$\text{PWM Period} = [(PRy) + 1] \cdot T_{CY} \cdot (\text{Timer Prescale Value})$$

where:

$$\text{PWM Frequency} = 1/\text{[PWM Period]}$$

**Note 1:** Based on  $T_{CY} = T_{OSC} * 2$ ; Doze mode and PLL are disabled.

**Note:** A PRy value of N will produce a PWM period of N + 1 time base count cycles. For example, a value of 7 written into the PRy register will yield a period consisting of 8 time base cycles.

### 15.3.2 PWM DUTY CYCLE

The PWM duty cycle is specified by writing to the OCxRS and OCxR registers. The OCxRS and OCxR registers can be written to at any time, but the duty cycle value is not latched until a match between PRy and TMRY occurs (i.e., the period is complete). This provides a double buffer for the PWM duty cycle and is essential for glitchless PWM operation.

Some important boundary parameters of the PWM duty cycle include:

- If OCxR, OCxRS and PRy are all loaded with 0000h, the OCx pin will remain low (0% duty cycle).
- If OCxRS is greater than PRy, the pin will remain high (100% duty cycle).

See [Example 15-1](#) for PWM mode timing details.

[Table 15-1](#) and [Table 15-2](#) show example PWM frequencies and resolutions for a device operating at 4 MIPS and 10 MIPS, respectively.

### EQUATION 15-2: CALCULATION FOR MAXIMUM PWM RESOLUTION<sup>(1)</sup>

$$\text{Maximum PWM Resolution (bits)} = \frac{\log_{10} \left( \frac{FCY}{FPWM \cdot (\text{Timer Prescale Value})} \right)}{\log_{10} 2} \text{ bits}$$

**Note 1:** Based on FCY = Fosc/2; Doze mode and PLL are disabled.

### EXAMPLE 15-1: PWM PERIOD AND DUTY CYCLE CALCULATIONS<sup>(1)</sup>

- Find the Timer Period register value for a desired PWM frequency of 52.08 kHz, where Fosc = 8 MHz with PLL (32 MHz device clock rate) and a Timer2 prescaler setting of 1:1.

$$TCY = 2 * TOSC = 62.5 \text{ ns}$$

$$\text{PWM Period} = 1/\text{PWM Frequency} = 1/52.08 \text{ kHz} = 19.2 \text{ ms}$$

$$\text{PWM Period} = (PR2 + 1) * TCY * (\text{Timer2 Prescale Value})$$

$$19.2 \mu\text{s} = (PR2 + 1) * 62.5 \text{ ns} * 1$$

$$PR2 = 306$$

- Find the maximum resolution of the duty cycle that can be used with a 52.08 kHz frequency and a 32 MHz device clock rate.

$$\text{PWM Resolution} = \log_{10}(FCY/FPWM)/\log_{10}2 \text{ bits}$$

$$= (\log_{10}(16 \text{ MHz}/52.08 \text{ kHz})/\log_{10}2) \text{ bits}$$

$$= 8.3 \text{ bits}$$

**Note 1:** Based on TCY = 2 \* Tosc; Doze mode and PLL are disabled.

**TABLE 15-1: EXAMPLE PWM FREQUENCIES AND RESOLUTIONS AT 4 MIPS (FCY = 4 MHz)<sup>(1)</sup>**

PWM Frequency	7.6 Hz	61 Hz	122 Hz	977 Hz	3.9 kHz	31.3 kHz	125 kHz

**NOTES:**

## 16.0 SERIAL PERIPHERAL INTERFACE (SPI)

**Note:** This data sheet summarizes the features of the PIC24FJ128GB204 family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to the “*dsPIC33/PIC24 Family Reference Manual*”, “**Serial Peripheral Interface (SPI) with Audio Codec Support**” (DS70005136) which is available from the Microchip web site ([www.microchip.com](http://www.microchip.com)).

The Serial Peripheral Interface (SPI) module is a synchronous serial interface useful for communicating with other peripheral or microcontroller devices. These peripheral devices may be serial EEPROMs, shift registers, display drivers, A/D Converters, etc. The SPI module is compatible with the Motorola® SPI and SIOP interfaces. All devices in the PIC24FJ128GB204 family include three SPI modules.

The module supports operation in two Buffer modes. In Standard Buffer mode, data is shifted through a single serial buffer. In Enhanced Buffer mode, data is shifted through a FIFO buffer. The FIFO level depends on the configured mode.

Variable length data can be transmitted and received, from 2 to 32 bits.

**Note:** Do not perform Read-Modify-Write operations (such as bit-oriented instructions) on the SPIxBUF register in either Standard or Enhanced Buffer mode.

The module also supports a basic framed SPI protocol while operating in either Master or Slave mode. A total of four framed SPI configurations are supported.

The module also supports Audio modes. Four different Audio modes are available.

- I<sup>2</sup>S mode
- Left Justified
- Right Justified
- PCM/DSP

In each of these modes, the serial clock is free-running and audio data is always transferred.

If an audio protocol data transfer takes place between two devices, then usually one device is the master and the other is the slave. However, audio data can be transferred between two slaves. Because the audio protocols require free-running clocks, the master can be a third party controller. In either case, the master generates two free-running clocks: SCKx and LRC (Left, Right Channel Clock/SSx/FSYNC).

The SPI serial interface consists of four pins:

- SDIx: Serial Data Input
- SDOx: Serial Data Output
- SCKx: Shift Clock Input or Output
- SSx: Active-Low Slave Select or Frame Synchronization I/O Pulse

The SPI module can be configured to operate using 2, 3 or 4 pins. In the 3-pin mode, SSx is not used. In the 2-pin mode, both SDOx and SSx are not used.

The SPI module has the ability to generate three interrupts, reflecting the events that occur during the data communication. The following types of interrupts can be generated:

1. Receive interrupts are signalled by SPIxRXIF. This event occurs when:
  - RX watermark interrupt
  - SPIROV = 1
  - SPIRBF = 1
  - SPIRBE = 1provided the respective mask bits are enabled in SPIxIMSKL/H.
2. Transmit interrupts are signalled by SPIxTXIF. This event occurs when:
  - TX watermark interrupt
  - SPITUR = 1
  - SPITBF = 1
  - SPITBE = 1provided the respective mask bits are enabled in SPIxIMSKL/H.
3. General interrupts are signalled by SPIxFIF. This event occurs when:
  - FRMERR = 1
  - SPIBUSY = 1
  - SRMT = 1provided the respective mask bits are enabled in SPIxIMSKL/H.

Block diagrams of the module in Standard and Enhanced modes are shown in [Figure 16-1](#) and [Figure 16-2](#).

**Note:** In this section, the SPI modules are referred to together as SPIx, or separately as SPI1, SPI2 or SPI3. Special Function Registers will follow a similar notation. For example, SPIxCON1L and SPIxCON1H refer to the control registers for any of the three SPI modules.

# PIC24FJ128GB204 FAMILY

## 16.1 Standard Master Mode

To set up the SPIx module for the Standard Master mode of operation:

1. If using interrupts:
  - a) Clear the interrupt flag bits in the respective IFSx register.
  - b) Set the interrupt enable bits in the respective IECx register.
  - c) Write the SPIxIP<2:0> bits in the respective IPCx register to set the interrupt priority.
2. Write the desired settings to the SPIxCON1L and SPIxCON1H registers with the MSTEN bit (SPIxCON1L<5>) = 1.
3. Clear the SPIROV bit (SPIxSTATL<6>).
4. Enable SPIx operation by setting the SPIEN bit (SPIxCON1L<15>).
5. Write the data to be transmitted to the SPIxBUFL and SPIxBUFH registers. Transmission (and reception) will start as soon as data is written to the SPIxBUFL and SPIxBUFH registers.

## 16.2 Standard Slave Mode

To set up the SPIx module for the Standard Slave mode of operation:

1. Clear the SPIxBUFL registers.
2. If using interrupts:
  - a) Clear the SPIxBUFL and SPIxBUFH registers.
  - b) Set the interrupt enable bits in the respective IECx register.
  - c) Write the SPIxIP<2:0> bits in the respective IPCx register to set the interrupt priority.
3. Write the desired settings to the SPIxCON1L, SPIxCON1H and SPIxCON2L registers with the MSTEN bit (SPIxCON1L<5>) = 0.
4. Clear the SMP bit.
5. If the CKE bit (SPIxCON1L<8>) is set, then the SSEN bit (SPIxCON1L<7>) must be set to enable the SSx pin.
6. Clear the SPIROV bit (SPIxSTATL<6>).
7. Enable SPIx operation by setting the SPIEN bit (SPIxCON1L<15>).

**FIGURE 16-1: SPIx MODULE BLOCK DIAGRAM (STANDARD MODE)**

## 16.3 Enhanced Slave Mode

To set up the SPIx module for the Enhanced Buffer Master mode of operation:

1. If using interrupts:
  - a) Clear the interrupt flag bits in the respective IFSx register.
  - b) Set the interrupt enable bits in the respective IECx register.
  - c) Write the SPIxIP<2:0> bits in the respective IPCx register.
2. Write the desired settings to the SPIxCON1L, SPIxCON1H and SPIxCON2L registers with MSTEN (SPIxCON1L<5>) = 1.
3. Clear the SPIROV bit (SPIxSTATL<6>).
4. Select Enhanced Buffer mode by setting the ENHBUF bit (SPIxCON1L<0>).
5. Enable SPIx operation by setting the SPIEN bit (SPIxCON1L<15>).
6. Write the data to be transmitted to the SPIxBUFL and SPIxBUFH registers. Transmission (and reception) will start as soon as data is written to the SPIxBUFL and SPIxBUFH registers.

## 16.4 Enhanced Master Mode

To set up the SPIx module for the Enhanced Buffer Slave mode of operation:

1. Clear the SPIxBUFL and SPIxBUFH registers.
2. If using interrupts:
  - a) Clear the interrupt flag bits in the respective IFSx register.
  - b) Set the interrupt enable bits in the respective IECx register.
  - c) Write the SPIxIP<2:0> bits in the respective IPCx register to set the interrupt priority.
3. Write the desired settings to the SPIxCON1L, SPIxCON1H and SPIxCON2L registers with the MSTEN bit (SPIxCON1L<5>) = 0.
4. Clear the SMP bit.
5. If the CKE bit is set, then the SSEN bit must be set, thus enabling the SSx pin.
6. Clear the SPIROV bit (SPIxSTATL<6>).
7. Select Enhanced Buffer mode by setting the ENHBUF bit (SPIxCON1L<0>).
8. Enable SPIx operation by setting the SPIEN bit (SPIxCON1L<15>).

**FIGURE 16-2: SPIx MODULE BLOCK DIAGRAM (ENHANCED MODE)**

# PIC24FJ128GB204 FAMILY

---

## 16.5 Audio Mode

To set up the SPIx module for the Audio mode:

1. Clear the SPIxBUFL and SPIxBUFH registers.
2. If using interrupts:
  - a) Clear the interrupt flag bits in the respective IFSx register.
  - b) Set the interrupt enable bits in the respective IECx register.
  - a) Write the SPIxIP<2:0> bits in the respective IPCx register to set the interrupt priority.
3. Write the desired settings to the SPIxCON1L, SPIxCON1H and SPIxCON2L registers with AUDEN (SPIxCON1H<15>) = 1.
4. Clear the SPIROV bit (SPIxSTATL<6>).
5. Enable SPIx operation by setting the SPIEN bit (SPIxCON1L<15>).
6. Write the data to be transmitted to the SPIxBUFL and SPIxBUFH registers. Transmission (and reception) will start as soon as data is written to the SPIxBUFL and SPIxBUFH registers.

## 16.6 Registers

The SPI module consists of the following Special Function Registers (SFRs):

- SPIxCON1L, SPIxCON1H and SPIxCON2L: SPIx Control Registers ([Register 16-1](#) through [Register 16-3](#))
- SPIxSTATL and SPIxSTATH: SPIx Status Registers ([Register 16-4](#) and [Register 16-5](#))
- SPIxBUFL and SPIxBUFH: SPIx Buffer Registers
- SPIxBRGL: SPIx Baud Rate Register
- SPIxIMSKL and SPIxIMSKH: SPIx Interrupt Mask Registers ([Register 16-6](#) and [Register 16-7](#))
- SPIxURDTL and SPIxURDTH: SPIx Underrun Data Registers

**NOTES:**

## 17.0 INTER-INTEGRATED CIRCUIT™ (I<sup>2</sup>C™)

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Inter-Integrated Circuit™ (I<sup>2</sup>C™)” (DS70000195). The information in this data sheet supersedes the information in the FRM.

The Inter-Integrated Circuit™ (I<sup>2</sup>C™) module is a serial interface useful for communicating with other peripheral or microcontroller devices. These peripheral devices may be serial EEPROMs, display drivers, A/D Converters, etc.

The I<sup>2</sup>C module supports these features:

- Independent master and slave logic
- 7-bit and 10-bit device addresses
- General call address as defined in the I<sup>2</sup>C protocol
- Clock stretching to provide delays for the processor to respond to a slave data request
- Both 100 kHz and 400 kHz bus specifications
- Configurable address masking
- Multi-Master modes to prevent loss of messages in arbitration
- Bus Repeater mode, allowing the acceptance of all messages as a slave regardless of the address
- Automatic SCL

A block diagram of the module is shown in [Figure 17-1](#).

## 17.1 Communicating as a Master in a Single Master Environment

The details of sending a message in Master mode depends on the communication protocols for the device being communicated with. Typically, the sequence of events is as follows:

1. Assert a Start condition on SDAx and SCLx.
2. Send the I<sup>2</sup>C device address byte to the slave with a write indication.
3. Wait for and verify an Acknowledge from the slave.
4. Send the first data byte (sometimes known as the command) to the slave.
5. Wait for and verify an Acknowledge from the slave.
6. Send the serial memory address low byte to the slave.
7. Repeat Steps 4 and 5 until all data bytes are sent.
8. Assert a Repeated Start condition on SDAx and SCLx.
9. Send the device address byte to the slave with a read indication.
10. Wait for and verify an Acknowledge from the slave.
11. Enable master reception to receive serial memory data.
12. Generate an ACK or NACK condition at the end of a received byte of data.
13. Generate a Stop condition on SDAx and SCLx.

# PIC24FJ128GB204 FAMILY

FIGURE 17-1: I<sup>2</sup>C™ BLOCK DIAGRAM

## 17.2 Setting Baud Rate When Operating as a Bus Master

To compute the Baud Rate Generator reload value, use [Equation 17-1](#).

### EQUATION 17-1: COMPUTING BAUD RATE RELOAD VALUE<sup>(1)</sup>

$$I2CxBRG = \left( \left( \frac{1}{F_{SCL}} - PGDX \right) \times \frac{FCY}{2} \right) - 2$$

**Note 1:** Based on  $FCY = Fosc/2$ ; Doze mode and PLL are disabled.

## 17.3 Slave Address Masking

The I2CxMSK register ([Register 17-4](#)) designates address bit positions as “don’t care” for both 7-Bit and 10-Bit Addressing modes. Setting a particular bit location (= 1) in the I2CxMSK register causes the slave module to respond, whether the corresponding address bit value is a ‘0’ or a ‘1’. For example, when I2CxMSK is set to ‘0010000000’, the slave module will detect both addresses, ‘000000000000’ and ‘0010000000’.

To enable address masking, the Intelligent Peripheral Management Interface (IPMI) must be disabled by clearing the STRICT bit (I2CxCONL<11>).

**Note:** As a result of changes in the I<sup>2</sup>C™ protocol, the addresses in [Table 17-1](#) are reserved and will not be Acknowledged in Slave mode. This includes any address mask settings that include any of these addresses.

**TABLE 17-1: I<sup>2</sup>C™ RESERVED ADDRESSES<sup>(1)</sup>**

Slave Address	R/W Bit	Description
0000 000	0	General Call Address <sup>(2)</sup>
0000 000	1	Start Byte
0000 001	x	Cbus Address
0000 01x	x	Reserved
0000 1xx	x	HS Mode Master Code
1111 0xx	x	10-Bit Slave Upper Byte <sup>(3)</sup>
1111 1xx	x	Reserved

**Note 1:** The address bits listed here will never cause an address match independent of address mask settings.

**2:** The address will be Acknowledged only if GCEN = 1.

**3:** A match on this address can only occur on the upper byte in 10-Bit Addressing mode.

# PIC24FJ128GB204 FAMILY

## 18.0 UNIVERSAL ASYNCHRONOUS RECEIVER TRANSMITTER (UART)

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “*dsPIC33/PIC24 Family Reference Manual*”, “**Universal Asynchronous Receiver Transmitter (UART)**” (DS70000582). The information in this data sheet supersedes the information in the FRM.

The Universal Asynchronous Receiver Transmitter (UART) module is one of the serial I/O modules available in the PIC24F device family. The UART is a full-duplex, asynchronous system that can communicate with peripheral devices, such as personal computers, LIN/J2602, RS-232 and RS-485 interfaces. The module also supports a hardware flow control option with the UxCTS and UxRTS pins. The UART module includes the ISO 7816 compliant Smart Card support and the IrDA® encoder/decoder unit.

The PIC24FJ128GB204 family devices are equipped with four UART modules, referred to as UART1, UART2, UART3 and UART4.

The primary features of the UARTx modules are:

- Full-Duplex, 8 or 9-Bit Data Transmission through the UxTX and UxRX Pins
- Even, Odd or No Parity Options (for 8-bit data)
- One or Two Stop bits
- Hardware Flow Control Option with the UxCTS and UxRTS Pins
- Fully Integrated Baud Rate Generator with 16-Bit Prescaler
- Baud Rates Range from 15 bps to 1 Mbps at 16 MIPS in 16x mode

- Baud Rates Range from 61 bps to 4 Mbps at 16 MIPS in 4x mode
- 4-Deep, First-In-First-Out (FIFO) Transmit Data Buffer
- 4-Deep FIFO Receive Data Buffer
- Parity, Framing and Buffer Overrun Error Detection
- Support for 9-Bit mode with Address Detect (9<sup>th</sup> bit = 1)
- Separate Transmit and Receive Interrupts
- Loopback mode for Diagnostic Support
- Polarity Control for Transmit and Receive Lines
- Support for Sync and Break Characters
- Supports Automatic Baud Rate Detection
- IrDA® Encoder and Decoder Logic
- Includes DMA Support
- 16x Baud Clock Output for IrDA Support
- Smart Card ISO 7816 Support (UART1 and UART2 only):
  - T = 0 protocol with automatic error handling
  - T = 1 protocol
  - Dedicated Guard Time Counter (GTC)
  - Dedicated Waiting Time Counter (WTC)

A simplified block diagram of the UARTx module is shown in [Figure 18-1](#). The UARTx module consists of these key important hardware elements:

- Baud Rate Generator
- Asynchronous Transmitter
- Asynchronous Receiver

**Note:** Throughout this section, references to register and bit names that may be associated with a specific UART module are referred to generically by the use of 'x' in place of the specific module number. Thus, "UxSTA" might refer to the Status register for either UART1, UART2, UART3 or UART4.

# PIC24FJ128GB204 FAMILY

FIGURE 18-1: UARTx SIMPLIFIED BLOCK DIAGRAM

- Note 1:** The UARTx inputs and outputs must all be assigned to available RPn/RPin pins before use. See [Section 11.4 “Peripheral Pin Select \(PPS\)”](#) for more information.
- 2:** The UxTX and UxRX pins need to be shorted to be used for the Smart Card interface; this should be taken care of by the user.

## 18.1 UARTx Baud Rate Generator (BRG)

The UARTx module includes a dedicated, 16-bit Baud Rate Generator. The UxBRG register controls the period of a free-running, 16-bit timer. [Equation 18-1](#) shows the formula for computation of the baud rate with BRGH = 0.

### EQUATION 18-1: UARTx BAUD RATE WITH BRGH = 0<sup>(1,2)</sup>

$$\text{Baud Rate} = \frac{FCY}{16 \cdot (UxBRG + 1)}$$

$$UxBRG = \frac{FCY}{16 \cdot \text{Baud Rate}} - 1$$

**Note 1:** FCY denotes the instruction cycle clock frequency (Fosc/2).

**2:** Based on FCY = Fosc/2; Doze mode and PLL are disabled.

[Example 18-1](#) shows the calculation of the baud rate error for the following conditions:

- FCY = 4 MHz
- Desired Baud Rate = 9600

The maximum baud rate (BRGH = 0) possible is FCY/16 (for UxBRG = 0) and the minimum baud rate possible is FCY/(16 \* 65536).

[Equation 18-2](#) shows the formula for computation of the baud rate with BRGH = 1.

### EQUATION 18-2: UARTx BAUD RATE WITH BRGH = 1<sup>(1,2)</sup>

$$\text{Baud Rate} = \frac{FCY}{4 \cdot (UxBRG + 1)}$$

$$UxBRG = \frac{FCY}{4 \cdot \text{Baud Rate}} - 1$$

**Note 1:** FCY denotes the instruction cycle clock frequency.

**2:** Based on FCY = Fosc/2; Doze mode and PLL are disabled.

The maximum baud rate (BRGH = 1) possible is FCY/4 (for UxBRG = 0) and the minimum baud rate possible is FCY/(4 \* 65536).

Writing a new value to the UxBRG register causes the BRG timer to be reset (cleared). This ensures the BRG does not wait for a timer overflow before generating the new baud rate.

### EXAMPLE 18-1: BAUD RATE ERROR CALCULATION (BRGH = 0)<sup>(1)</sup>

$$\text{Desired Baud Rate} = FCY/(16 (UxBRG + 1))$$

Solving for UxBRG Value:

$$UxBRG = ((FCY/\text{Desired Baud Rate})/16) - 1$$

$$UxBRG = ((4000000/9600)/16) - 1$$

$$UxBRG = 25$$

$$\text{Calculated Baud Rate} = 4000000/(16 (25 + 1))$$

$$= 9615$$

$$\text{Error} = (\text{Calculated Baud Rate} - \text{Desired Baud Rate})$$

$$\text{Desired Baud Rate}$$

$$= (9615 - 9600)/9600$$

$$= 0.16\%$$

**Note 1:** Based on FCY = Fosc/2; Doze mode and PLL are disabled.

# PIC24FJ128GB204 FAMILY

---

## 18.2 Transmitting in 8-Bit Data Mode

1. Set up the UARTx:
  - a) Write appropriate values for data, parity and Stop bits.
  - b) Write appropriate baud rate value to the UxBRG register.
  - c) Set up transmit and receive interrupt enable and priority bits.
2. Enable the UARTx.
3. Set the UTXEN bit (causes a transmit interrupt, two cycles after being set).
4. Write a data byte to the lower byte of the UxTXREG word. The value will be immediately transferred to the Transmit Shift Register (TSR) and the serial bit stream will start shifting out with the next rising edge of the baud clock.
5. Alternatively, the data byte may be transferred while UTXEN = 0 and then, the user may set UTXEN. This will cause the serial bit stream to begin immediately because the baud clock will start from a cleared state.
6. A transmit interrupt will be generated as per interrupt control bits, UTXISEL<1:0>.

## 18.3 Transmitting in 9-Bit Data Mode

1. Set up the UARTx (as described in [Section 18.2 "Transmitting in 8-Bit Data Mode"](#)).
2. Enable the UARTx.
3. Set the UTXEN bit (causes a transmit interrupt).
4. Write UxTXREG as a 16-bit value only.
5. A word write to UxTXREG triggers the transfer of the 9-bit data to the TSR. The serial bit stream will start shifting out with the first rising edge of the baud clock.
6. A transmit interrupt will be generated as per the setting of control bits, UTXISEL<1:0>.

## 18.4 Break and Sync Transmit Sequence

The following sequence will send a message frame header, made up of a Break, followed by an auto-baud Sync byte.

1. Configure the UARTx for the desired mode.
2. Set UTXEN and UTXBRK to set up the Break character.
3. Load the UxTXREG with a dummy character to initiate transmission (value is ignored).
4. Write '55h' to UxTXREG; this loads the Sync character into the transmit FIFO.
5. After the Break has been sent, the UTXBRK bit is reset by hardware. The Sync character now transmits.

## 18.5 Receiving in 8-Bit or 9-Bit Data Mode

1. Set up the UARTx (as described in [Section 18.2 "Transmitting in 8-Bit Data Mode"](#)).
2. Enable the UARTx.
3. Set the URXEN bit (UxSTA<12>).
4. A receive interrupt will be generated when one or more data characters have been received as per interrupt control bits, URXISEL<1:0>.
5. Read the OERR bit to determine if an overrun error has occurred. The OERR bit must be reset in software.
6. Read UxRXREG.

The act of reading the UxRXREG character will move the next character to the top of the receive FIFO, including a new set of PERR and FERR values.

## 18.6 Operation of UxCTS and UxRTS Control Pins

UARTx Clear-to-Send (UxCTS) and Request-to-Send (UxRTS) are the two hardware controlled pins that are associated with the UARTx modules. These two pins allow the UARTx to operate in Simplex and Flow Control mode. They are implemented to control the transmission and reception between the Data Terminal Equipment (DTE). The UEN<1:0> bits in the UxMODE register configure these pins.

## 18.7 Infrared Support

The UARTx module provides two types of infrared UART support: one is the IrDA clock output to support an external IrDA encoder and decoder device (legacy module support), and the other is the full implementation of the IrDA encoder and decoder. Note that because the IrDA modes require a 16x baud clock, they will only work when the BRGH bit (UxMODE<3>) is '0'.

### 18.7.1 IrDA CLOCK OUTPUT FOR EXTERNAL IrDA SUPPORT

To support external IrDA encoder and decoder devices, the BCLKx pin (same as the UxRTS pin) can be configured to generate the 16x baud clock. With UEN<1:0> = 11, the BCLKx pin will output the 16x baud clock if the UARTx module is enabled. It can be used to support the IrDA codec chip.

## 18.7.2 BUILT-IN IrDA ENCODER AND DECODER

The UARTx has full implementation of the IrDA encoder and decoder as part of the UARTx module. The built-in IrDA encoder and decoder functionality is enabled using the IREN bit ( $UxMODE<12>$ ). When enabled ( $IREN = 1$ ), the receive pin ( $UxRX$ ) acts as the input from the infrared receiver. The transmit pin ( $UxTX$ ) acts as the output to the infrared transmitter.

## 18.8 Smart Card ISO 7816 Support

[Figure 18-2](#) shows a Smart Card subsystem using a PIC24F microcontroller with a UARTx module for Smart Card data communication. Vcc to power the Smart Card can be supplied through a terminal or an

external power supply. The terminal is also responsible for clocking and resetting the Smart Card. The TX and RX line of the PIC24F device has to be shorted externally, and then connected to the I/O line of the Smart Card.

There are two protocols which are widely used for Smart Card communication between terminal and Smart Card:

- $T = 0$  (asynchronous, half-duplex, byte-oriented protocol)
- $T = 1$  (asynchronous, half-duplex, block-oriented protocol)

The selection of the  $T = 0$  or  $T = 1$  protocol is done using the PTRCL bit in the UxSCCON register.

**FIGURE 18-2: SMART CARD SUBSYSTEM CONNECTION**

# PIC24FJ128GB204 FAMILY

## 18.9 Control Registers

The UART module consists of the following Special Function Registers (SFRs):

- UxMODE: UARTx Mode Register ([Register 18-1](#))
- UxSTA: UARTx Status and Control Register ([Register 18-2](#))
- UxRXREG: UARTx Receive Register
- UxTXREG: UARTx Transmit Register (Write-Only) ([Register 18-3](#))
- UxADMD: UARTx Address Mask Detect Register ([Register 18-4](#))

- UxBRG: UARTx Baud Rate Register
- UxSCCON: UARTx Smart Card Control Register ([Register 18-5](#))
- UxSCINT: UARTx Smart Card Interrupt Register ([Register 18-6](#))
- UxGTC: UARTx Guard Time Counter
- UxWTCL and UxWTCH: UARTx Waiting Time Counter Low/High

## 19.0 UNIVERSAL SERIAL BUS WITH ON-THE-GO SUPPORT (USB OTG)

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “*dsPIC33/PIC24 Family Reference Manual*”, “**USB On-The-Go (OTG)**” (DS39721). The information in this data sheet supersedes the information in the FRM.

PIC24FJ128GB204 family devices contain a full-speed and low-speed compatible, On-The-Go (OTG) USB Serial Interface Engine (SIE). The OTG capability allows the device to act either as a USB peripheral device or as a USB embedded host with limited host capabilities. The OTG capability allows the device to dynamically switch from device to host operation using OTG’s Host Negotiation Protocol (HNP).

For more details on OTG operation, refer to the “*On-The-Go Supplement*” to the “*USB 2.0 Specification*”, published by the USB-IF. For more details on USB operation, refer to the “*Universal Serial Bus Specification*”, v2.0.

The USB OTG module offers these features:

- USB functionality in Device and Host modes, and OTG capabilities for application-controlled mode switching
- Software-selectable module speeds of full speed (12 Mbps) or low speed (1.5 Mbps, available in Host mode only)
- Support for all four USB transfer types: control, interrupt, bulk and isochronous
- Sixteen bidirectional endpoints for a total of 32 unique endpoints
- DMA interface for data RAM access
- Queues up to sixteen unique endpoint transfers without servicing
- Integrated, on-chip USB transceiver
- Integrated VBUS generation with on-chip comparators and boost generation
- Configurations for on-chip bus pull-up and pull-down resistors

A simplified block diagram of the USB OTG module is shown in [Figure 19-1](#).

The USB OTG module can function as a USB peripheral device or as a USB host, and may dynamically switch between Device and Host modes under software control. In either mode, the same data paths and Buffer Descriptors (BDs) are used for the transmission and reception of data.

In discussing USB operation, this section will use a controller-centric nomenclature for describing the direction of the data transfer between the microcontroller and the USB. RX (Receive) will be used to describe transfers that move data from the USB to the microcontroller and TX (Transmit) will be used to describe transfers that move data from the microcontroller to the USB. [Table 19-1](#) shows the relationship between data direction in this nomenclature and the USB tokens exchanged.

**TABLE 19-1: CONTROLLER-CENTRIC DATA DIRECTION FOR USB HOST OR TARGET**

USB Mode	Direction	
	RX	TX
Device	OUT or SETUP	IN
Host	IN	OUT or SETUP

This chapter presents the most basic operations needed to implement USB OTG functionality in an application. A complete and detailed discussion of the USB protocol and its OTG supplement are beyond the scope of this data sheet. It is assumed that the user already has a basic understanding of USB architecture and the latest version of the protocol.

Not all steps for proper USB operation (such as device enumeration) are presented here. It is recommended that application developers use an appropriate device driver to implement all of the necessary features. Microchip provides a number of application-specific resources, such as USB firmware and driver support. Refer to [www.microchip.com/usb](http://www.microchip.com/usb) for the latest firmware and driver support.

# PIC24FJ128GB204 FAMILY

FIGURE 19-1: USB OTG MODULE BLOCK DIAGRAM

## 19.1 Hardware Configuration

### 19.1.1 DEVICE MODE

#### 19.1.1.1 D+ Pull-up Resistor

PIC24FJ128GB204 family devices have a built-in 1.5 kΩ resistor on the D+ line that is available when the microcontroller is operating in Device mode. This is used to signal an external host that the device is operating in Full-Speed Device mode. It is engaged by setting the USBEN bit (U1CON<0>). If the OTGEN bit (U1OTGCON<2>) is set, then the D+ pull-up is enabled through the DPPULUP bit (U1OTGCON<7>).

Alternatively, an external resistor may be used on D+, as shown in [Figure 19-2](#).

**FIGURE 19-2: EXTERNAL PULL-UP FOR FULL-SPEED DEVICE MODE**

#### 19.1.1.2 Power Modes

Many USB applications will likely have several different sets of power requirements and configuration. The most common power modes encountered are:

- Bus Power Only mode
- Self-Power Only mode
- Dual Power with Self-Power Dominance mode

Bus Power Only mode ([Figure 19-3](#)) is effectively the simplest method. All power for the application is drawn from the USB.

To meet the inrush current requirements of the “*USB 2.0 Specification*”, the total effective capacitance appearing across VBUS and ground must be no more than 10 µF.

In the USB Suspend mode, devices must consume no more than 2.5 mA from the 5V VBUS line of the USB cable. During the USB Suspend mode, the D+ or D- pull-up resistor must remain active, which will consume some of the allowed suspend current.

In Self-Power Only mode ([Figure 19-4](#)), the USB application provides its own power, with very little power being pulled from the USB. Note that an attach indication is added to indicate when the USB has been connected and the host is actively powering VBUS.

To meet compliance specifications, the USB module (and the D+ or D- pull-up resistor) should not be enabled until the host actively drives VBUS high. One of the 5.5V tolerant I/O pins may be used for this purpose.

The application should never source any current onto the 5V VBUS pin of the USB cable.

The Dual Power with Self-Power Dominance mode ([Figure 19-5](#)) allows the application to use internal power primarily, but switch to power from the USB when no internal power is available. Dual power devices must also meet all of the special requirements for inrush current and Suspend mode current previously described, and must not enable the USB module until VBUS is driven high.

**FIGURE 19-3: BUS POWER ONLY**

**FIGURE 19-4: SELF-POWER ONLY**

**FIGURE 19-5: DUAL POWER EXAMPLE**

# PIC24FJ128GB204 FAMILY

## 19.1.2 HOST AND OTG MODES

### 19.1.2.1 D+ and D- Pull-Down Resistors

PIC24FJ128GB204 family devices have a built-in  $15\text{ k}\Omega$  pull-down resistor on the D+ and D- lines. These are used in tandem to signal to the bus that the microcontroller is operating in Host mode. They are engaged by setting the HOSTEN bit (U1CON<3>). If the OTGEN bit (U1OTGCON<2>) is set, then these pull-downs are enabled by setting the DPPULDWN and DMPULDWN bits (U1OTGCON<5:4>).

### 19.1.2.2 Power Configurations

In Host mode, as well as Host mode in On-The-Go operation, the “*USB 2.0 Specification*” requires that the host application should supply power on VBUS. Since the microcontroller is running below VBUS, and is not able to source sufficient current, a separate power supply must be provided.

When the application is always operating in Host mode, a simple circuit can be used to supply VBUS and regulate current on the bus (Figure 19-6). For OTG operation, it is necessary to be able to turn VBUS on or off as needed, as the microcontroller switches between Device and Host modes. A typical example using an external charge pump is shown in Figure 19-7.

FIGURE 19-6: USB HOST INTERFACE EXAMPLE

FIGURE 19-7: USB OTG INTERFACE EXAMPLE

### 19.1.2.3 VBUS Voltage Generation with External Devices

When operating as a USB host, either as an A-device in an OTG configuration or as an embedded host, VBUS must be supplied to the attached device. PIC24FJ128GB204 family devices have an internal VBUS boost assist to help generate the required 5V VBUS from the available voltages on the board. This is comprised of a simple PWM output to control a Switch mode power supply, and built-in comparators to monitor output voltage and limit current.

To enable voltage generation:

1. Verify that the USB module is powered ( $U1PWRC<0> = 1$ ) and that the VBUS discharge is disabled ( $U1OTGCON<0> = 0$ ).
2. Select the desired target voltage using the VBUSCHG bit ( $U1OTGCON<1>$ ).
3. Enable the VBUS generation circuit ( $U1OTGCON<3> = 1$ ).

**Note:** This section describes the general process for VBUS voltage generation and control. Please refer to the "dsPIC33/PIC24 Family Reference Manual" for additional examples.

### 19.1.3 CALCULATING TRANSCEIVER POWER REQUIREMENTS

The USB transceiver consumes a variable amount of current depending on the characteristic impedance of the USB cable, the length of the cable, the  $V_{USB3V3}$  supply voltage and the actual data patterns moving across the USB cable. Longer cables have larger capacitances and consume more total energy when switching output states. The total transceiver current consumption will be application-specific. [Equation 19-1](#) can help estimate how much current actually may be required in full-speed applications.

Refer to the "dsPIC33/PIC24 Family Reference Manual", "USB On-The-Go (OTG)" (DS39721) for a complete discussion on transceiver power consumption.

### EQUATION 19-1: ESTIMATING USB TRANSCEIVER CURRENT CONSUMPTION

$$I_{CVR} = \frac{40 \text{ mA} \cdot V_{USB3V3} \cdot P_{ZERO} \cdot P_{IN} \cdot L_{CABLE}}{3.3V \cdot 5m} + I_{PULLUP}$$

**Legend:**  $V_{USB3V3}$  – Voltage applied to the  $V_{USB3V3}$  pin in volts (3.0V to 3.6V).

$P_{ZERO}$  – Percentage (in decimal) of the IN traffic bits sent by the PIC® microcontroller that are a value of '0'.

$P_{IN}$  – Percentage (in decimal) of total bus bandwidth that is used for In traffic.

$L_{CABLE}$  – Length (in meters) of the USB cable. The "USB 2.0 Specification" requires that full-speed applications use cables no longer than 5m.

$I_{PULLUP}$  – Current which the nominal, 1.5 kΩ pull-up resistor (when enabled) must supply to the USB cable.

# PIC24FJ128GB204 FAMILY

## 19.2 USB Buffer Descriptors and the BDT

Endpoint buffer control is handled through a structure called the Buffer Descriptor Table (BDT). This provides a flexible method for users to construct and control endpoint buffers of various lengths and configurations.

The BDT can be located in any available, 512-byte aligned block of data RAM. The BDT Pointer (U1BDTP1) contains the upper address byte of the BDT and sets the location of the BDT in RAM. The user must set this pointer to indicate the table's location.

The BDT is composed of Buffer Descriptors (BDs) which are used to define and control the actual buffers in the USB RAM space. Each BD consists of two, 16-bit "soft" (non-fixed address) registers, BDnSTAT and BDnADR, where n represents one of the 64 possible BDs (range of 0 to 63). BDnSTAT is the status register for BDn, while BDnADR specifies the starting address for the buffer associated with BDn.

**Note:** Since BDnADR is a 16-bit register, only the first 64 Kbytes of RAM can be accessed by the USB module.

Depending on the endpoint buffering configuration used, there are up to 64 sets of Buffer Descriptors, for a total of 256 bytes. At a minimum, the BDT must be at least 8 bytes long. This is because the "USB 2.0 Specification" mandates that every device must have Endpoint 0 with both input and output for initial setup.

Endpoint mapping in the BDT is dependent on three variables:

- Endpoint number (0 to 15)
- Endpoint direction (RX or TX)
- Ping-pong settings (U1CNFG1<1:0>)

[Figure 19-8](#) illustrates how these variables are used to map endpoints in the BDT.

In Host mode, only Endpoint 0 Buffer Descriptors are used. All transfers utilize the Endpoint 0 Buffer Descriptor and USB Endpoint Control register (U1EP0). For received packets, the attached device's source endpoint is indicated by the value of ENDPT<3:0> in the USB Status register (U1STAT<7:4>). For transmitted packets, the attached device's destination endpoint is indicated by the value written to the USB Token register (U1TOK).

**FIGURE 19-8: BDT MAPPING FOR ENDPOINT BUFFERING MODES**

BDs have a fixed relationship to a particular endpoint, depending on the buffering configuration. [Table 19-2](#) provides the mapping of BDs to endpoints. This relationship also means that gaps may occur in the BDT if endpoints are not enabled contiguously. This, theoretically, means that the BDs for disabled endpoints could be used as buffer space. In practice, users should avoid using such spaces in the BDT unless a method of validating BD addresses is implemented.

### 19.2.1 BUFFER OWNERSHIP

Because the buffers and their BDs are shared between the CPU and the USB module, a simple semaphore mechanism is used to distinguish which is allowed to update the BD and associated buffers in memory. This is done by using the UOWN bit as a semaphore to distinguish which is allowed to update the BD and associated buffers in memory. UOWN is the only bit that is shared between the two configurations of BDnSTAT.

When UOWN is clear, the BD entry is “owned” by the microcontroller core. When the UOWN bit is set, the BD entry and the buffer memory are “owned” by the USB peripheral. The core should not modify the BD or its

corresponding data buffer during this time. Note that the microcontroller core can still read BDnSTAT while the SIE owns the buffer and vice versa.

The Buffer Descriptors have a different meaning based on the source of the register update. [Register 19-1](#) and [Register 19-2](#) show the differences in BDnSTAT depending on its current “ownership”.

When UOWN is set, the user can no longer depend on the values that were written to the BDs. From this point, the USB module updates the BDs as necessary, overwriting the original BD values. The BDnSTAT register is updated by the SIE with the token PID and the transfer count is updated.

### 19.2.2 DMA INTERFACE

The USB OTG module uses a dedicated DMA to access both the BDT and the endpoint data buffers. Since part of the address space of the DMA is dedicated to the Buffer Descriptors, a portion of the memory connected to the DMA must comprise a contiguous address space, properly mapped for the access by the module.

**TABLE 19-2: ASSIGNMENT OF BUFFER DESCRIPTORS FOR THE DIFFERENT BUFFERING MODES**

Endpoint	BDs Assigned to Endpoint

<b>Legend:</b>	r = Reserved bit	HSC = Hardware Settable/Clearable bit
R = Readable bit	W = Writable bit	U = Unimplemented bit, read as '0'
-n = Value at POR	'1' = Bit is set	'r' = Reserved bit
		x = Bit is unknown

- bit 15      **UOWN:** USB Own bit  
0 = The microcontroller core owns the BD and its corresponding buffer; the USB module ignores all other fields in the BD
- bit 14      **DTS:** Data Toggle Packet bit<sup>(1)</sup>  
1 = Data 1 packet  
0 = Data 0 packet
- bit 13-12    **Reserved:** Maintain as '0'
- bit 11       **DTSEN:** Data Toggle Synchronization Enable bit  
1 = Data toggle synchronization is enabled; data packets with incorrect Sync value will be ignored  
0 = No data toggle synchronization is performed
- bit 10       **BSTALL:** Buffer STALL Enable bit  
1 = Buffer STALL is enabled; STALL handshake is issued if a token is received that would use the BD in the given location (UOWN bit remains set, BD value is unchanged); corresponding EPSTALL bit will get set on any STALL handshake  
0 = Buffer STALL is disabled
- bit 9-0       **BC<9:0>:** Byte Count bits  
This represents the number of bytes to be transmitted or the maximum number of bytes to be received during a transfer. Upon completion, the byte count is updated by the USB module with the actual number of bytes transmitted or received.

**Note 1:** This bit is ignored unless DTSEN = 1.

# PIC24FJ128GB204 FAMILY

## 19.3 USB Interrupts

The USB OTG module has many conditions that can be configured to cause an interrupt. All interrupt sources use the same interrupt vector.

Figure 19-9 shows the interrupt logic for the USB module. There are two layers of interrupt registers in the USB module. The top level consists of overall USB status interrupts; these are enabled and flagged in the U1IE and U1IR registers, respectively. The second

level consists of USB error conditions, which are enabled and flagged in the U1EIR and U1EIE registers. An interrupt condition in any of these triggers a USB Error Interrupt Flag (UERRIF) in the top level.

Interrupts may be used to trap routine events in a USB transaction. Figure 19-10 provides some common events within a USB frame and their corresponding interrupts.

FIGURE 19-9: USB OTG INTERRUPT FUNNEL

### 19.3.1 CLEARING USB OTG INTERRUPTS

Unlike device-level interrupts, the USB OTG interrupt status flags are not freely writable in software. All USB OTG flag bits are implemented as hardware settable only bits. Additionally, these bits can only be cleared in

software by writing a '1' to their locations (i.e., performing a `MOV` type instruction). Writing a '0' to a flag bit (i.e., a `BCLR` instruction) has no effect.

**Note:** Throughout this data sheet, a bit that can only be cleared by writing a '1' to its location is referred to as: "Write '1' to clear". In register descriptions, this function is indicated by the descriptor, "K".

**FIGURE 19-10: EXAMPLE OF A USB TRANSACTION AND INTERRUPT EVENTS**

## 19.4 Device Mode Operation

The following section describes how to perform a common Device mode task. In Device mode, USB transfers are performed at the transfer level. The USB module automatically performs the status phase of the transfer.

### 19.4.1 ENABLING DEVICE MODE

1. Reset the Ping-Pong Buffer Pointers by setting, then clearing, the Ping-Pong Buffer Reset bit, PPBRST (U1CON<1>).
2. Disable all interrupts (U1IE and U1EIE = 00h).
3. Clear any existing interrupt flags by writing FFh to U1IR and U1EIR.
4. Verify that VBUS is present (non-OTG devices only).

5. Enable the USB module by setting the USBEN bit (U1CON<0>).
6. Set the OTGEN bit (U1OTGCON<2>) to enable OTG operation.
7. Enable the Endpoint 0 buffer to receive the first setup packet by setting the EPRXEN and EPHSHK bits for Endpoint 0 (U1EP0<3,0> = 1).
8. Power up the USB module by setting the USBPWR bit (U1PWRC<0>).
9. Enable the D+ pull-up resistor to signal an attach by setting the DPPULUP bit (U1OTGCON<7>).

# PIC24FJ128GB204 FAMILY

---

## 19.4.2 RECEIVING AN IN TOKEN IN DEVICE MODE

1. Attach to a USB host and enumerate as described in Chapter 9 of the “*USB 2.0 Specification*”.
2. Create a data buffer and populate it with the data to send to the host.
3. In the appropriate (Even or Odd) TX BD for the desired endpoint:
  - a) Set up the status register (BDnSTAT) with the correct data toggle (DATA0/1) value and the byte count of the data buffer.
  - b) Set up the address register (BDnADR) with the starting address of the data buffer.
  - c) Set the UOWN bit of the status register to ‘1’.
4. When the USB module receives an IN token, it automatically transmits the data in the buffer. Upon completion, the module updates the status register (BDnSTAT) and sets the Transfer Done Interrupt Flag, TRNIF (U1IR<3>).

## 19.4.3 RECEIVING AN OUT TOKEN IN DEVICE MODE

1. Attach to a USB host and enumerate as described in Chapter 9 of the “*USB 2.0 Specification*”.
2. Create a data buffer with the amount of data you are expecting from the host.
3. In the appropriate (Even or Odd) TX BD for the desired endpoint:
  - a) Set up the status register (BDnSTAT) with the correct data toggle (DATA0/1) value and the byte count of the data buffer.
  - b) Set up the address register (BDnADR) with the starting address of the data buffer.
  - c) Set the UOWN bit of the status register to ‘1’.
4. When the USB module receives an OUT token, it automatically receives the data sent by the host to the buffer. Upon completion, the module updates the status register (BDnSTAT) and sets the Transfer Done Interrupt Flag, TRNIF (U1IR<3>).

## 19.5 Host Mode Operation

The following sections describe how to perform common Host mode tasks. In Host mode, USB transfers are invoked explicitly by the host software. The host software is responsible for the Acknowledge portion of the transfer. Also, all transfers are performed using the USB Endpoint 0 Control register (U1EP0) and Buffer Descriptors.

### 19.5.1 ENABLE HOST MODE AND DISCOVER A CONNECTED DEVICE

1. Enable Host mode by setting the HOSTEN bit (U1CON<3>). This causes the Host mode control bits in other USB OTG registers to become available.
2. Enable the D+ and D- pull-down resistors by setting the DPPULDN and DMPULDN bits (U1OTGCON<5:4>). Disable the D+ and D- pull-up resistors by clearing the DPPULUP and DMPULUP bits (U1OTGCON<7:6>).
3. At this point, Start-of-Frame (SOF) generation begins with the SOF counter loaded with 12,000. Eliminate noise on the USB by clearing the SOFEN bit (U1CON<0>) to disable Start-of-Frame packet generation.
4. Enable the device attached interrupt by setting the ATTACHIE bit (U1IE<6>).
5. Wait for the device attached interrupt (U1IR<6> = 1). This is signaled by the USB device changing the state of D+ or D- from ‘0’ to ‘1’ (SE0 to J-state). After it occurs, wait 100 ms for the device power to stabilize.
6. Check the state of the JSTATE and SE0 bits in U1CON. If the JSTATE bit (U1CON<7>) is ‘0’, the connecting device is low speed. If the connecting device is low speed, set the LSPDEN and LSPD bits (U1ADDR<7> and U1EP0<7>, respectively) to enable low-speed operation.
7. Reset the USB device by setting the USBRST bit (U1CON<4>) for at least 50 ms, sending Reset signaling on the bus. After 50 ms, terminate the Reset by clearing USBRST.
8. In order to keep the connected device from going into suspend, enable the SOF packet generation by setting the SOFEN bit.
9. Wait 10 ms for the device to recover from Reset.
10. Perform enumeration as described by Chapter 9 of the “*USB 2.0 Specification*”.

## 19.5.2 COMPLETE A CONTROL TRANSACTION TO A CONNECTED DEVICE

1. Follow the procedure described in [Section 19.5.1 “Enable Host Mode and Discover a Connected Device”](#) to discover a device.
2. Set up the Endpoint Control register for bidirectional control transfers by writing 0Dh to U1EP0 (this sets the EPCONDIS, EPTXEN and EPHSHK bits).
3. Place a copy of the device framework setup command in a memory buffer. See Chapter 9 of the “*USB 2.0 Specification*” for information on the device framework command set.
4. Initialize the Buffer Descriptor (BD) for the current (Even or Odd) TX EP0 to transfer the eight bytes of command data for a device framework command (i.e., `GET DEVICE DESCRIPTOR`):
  - a) Set the BD Data Buffer Address (BD0ADR) to the starting address of the 8-byte memory buffer containing the command.
  - b) Write 8008h to BD0STAT (this sets the UOWN bit and sets a byte count of 8).
5. Set the USB device address of the target device in the USB Address register (U1ADDR<6:0>). After a USB bus Reset, the device USB address will be zero. After enumeration, it will be set to another value, between 1 and 127.
6. Write D0h to U1TOK; this is a SETUP token to Endpoint 0, the target device’s default control pipe. This initiates a SETUP token on the bus, followed by a data packet. The device handshake is returned in the PID field of BD0STAT after the packets are complete. When the USB module updates BD0STAT, a Transfer Done Interrupt Flag is asserted (the TRNIF flag is set). This completes the setup phase of the setup transaction, as referenced in Chapter 9 of the “*USB 2.0 Specification*”.
7. To initiate the data phase of the setup transaction (i.e., get the data for the `GET DEVICE DESCRIPTOR` command), set up a buffer in memory to store the received data.
8. Initialize the current (Even or Odd) RX or TX (RX for IN, TX for OUT) EP0 BD to transfer the data.
  - a) Write C040h to BD0STAT. This sets the UOWN, configures Data Toggle Packet (DTS) to DATA1 and sets the byte count to the length of the data buffer (64 or 40h in this case).
  - b) Set BD0ADR to the starting address of the data buffer.
9. Write the USB Token register with the appropriate IN or OUT token to Endpoint 0, the target device’s default control pipe (e.g., write 90h to U1TOK for an IN token for a `GET DEVICE DESCRIPTOR` command). This initiates an IN token on the bus, followed by a data packet from the device to the host. When the data packet completes, the BD0STAT is written and a Transfer Done Interrupt Flag is asserted (the TRNIF flag is set). For control transfers with a single packet data phase, this completes the data phase of the setup transaction, as referenced in Chapter 9 of the “*USB 2.0 Specification*”. If more data needs to be transferred, return to Step 8.
10. To initiate the status phase of the setup transaction, set up a buffer in memory to receive or send the zero length status phase data packet.
11. Initialize the current (Even or Odd) TX EP0 BD to transfer the status data:
  - a) Set the BDT buffer address field to the starting address of the data buffer.
  - b) Write 8000h to BD0STAT (set UOWN bit, configure DTS to DATA0 and set byte count to 0).
12. Write the USB Token register with the appropriate IN or OUT token to Endpoint 0, the target device’s default control pipe (e.g., write 01h to U1TOK for an OUT token for a `GET DEVICE DESCRIPTOR` command). This initiates an OUT token on the bus, followed by a zero length data packet from the host to the device. When the data packet completes, the BD is updated with the handshake from the device and a Transfer Done interrupt Flag is asserted (the TRNIF flag is set). This completes the status phase of the setup transaction as described in Chapter 9 of the “*USB 2.0 Specification*”.

**Note:** Only one control transaction can be performed per frame.

# PIC24FJ128GB204 FAMILY

---

## 19.5.3 SEND A FULL-SPEED BULK DATA TRANSFER TO A TARGET DEVICE

1. Follow the procedure described in [Section 19.5.1 “Enable Host Mode and Discover a Connected Device”](#) and [Section 19.5.2 “Complete a Control Transaction to a Connected Device”](#) to discover and configure a device.
2. To enable transmit and receive transfers with handshaking enabled, write 1Dh to U1EP0. If the target device is a low-speed device, also set the LSPD (U1EP0<7>) bit. If you want the hardware to automatically retry indefinitely, if the target device asserts a NAK on the transfer, clear the Retry Disable bit, RETRYDIS (U1EP0<6>).
3. Set up the BD for the current (Even or Odd) TX EP0 to transfer up to 64 bytes.
4. Set the USB device address of the target device in the USB Address register (U1ADDR<6:0>).
5. Write an OUT token to the desired endpoint to U1TOK. This triggers the module's transmit state machines to begin transmitting the token and the data.
6. Wait for the Transfer Done Interrupt Flag, TRNIF. This indicates that the BD has been released back to the microprocessor and the transfer has completed. If the Retry Disable bit (RETRYDIS) is set, the handshake (ACK, NAK, STALL or ERROR (0Fh)) is returned in the BD PID field. If a STALL interrupt occurs, the pending packet must be dequeued and the error condition in the target device cleared. If a detach interrupt occurs (SE0 for more than 2.5 µs), then the target has detached (U1IR<0> is set).
7. Once the Transfer Done Interrupt Flag occurs (TRNIF is set), the BD can be examined and the next data packet queued by returning to Step 2.

**Note:** USB speed, transceiver and pull-ups should only be configured during the module setup phase. It is not recommended to change these settings while the module is enabled.

## 19.6 OTG Operation

### 19.6.1 SESSION REQUEST PROTOCOL (SRP)

An OTG A-device may decide to power down the VBUS supply when it is not using the USB link through the Session Request Protocol (SRP). Software may do this by clearing VBUSON (U1OTGCON<3>). When the VBUS supply is powered down, the A-device is said to have ended a USB session.

An OTG A-device or embedded host may repower the VBUS supply at any time (initiate a new session). An OTG B-device may also request that the OTG A-device repower the VBUS supply (initiate a new session). This is accomplished via the Session Request Protocol (SRP).

Prior to requesting a new session, the B-device must first check that the previous session has definitely ended. To do this, the B-device must check for two conditions:

1. VBUS supply is below the session valid voltage.
2. Both D+ and D- have been low for at least 2 ms.

The B-device will be notified of Condition 1 by the SESENDIF (U1OTGIR<2>) interrupt. Software will have to manually check for Condition 2.

**Note:** When the A-device powers down the VBUS supply, the B-device must disconnect its pull-up resistor from power. If the device is self-powered, it can do this by clearing DPPULUP (U1OTGCON<7>) and DMPULUP (U1OTGCON<6>).

The B-device may aid in achieving Condition 1 by discharging the VBUS supply through a resistor. Software may do this by setting VBUSDIS (U1OTGCON<0>).

After these initial conditions are met, the B-device may begin requesting the new session. The B-device begins by pulsing the D+ data line. Software should do this by setting DPPULUP (U1OTGCON<7>). The data line should be held high for 5 to 10 ms.

The B-device then proceeds by pulsing the VBUS supply. Software should do this by setting PUVBUS (U1CNFG2<4>). When an A-device detects SRP signaling (either via the ATTACHIF (U1IR<6>) interrupt or via the SESVDIF (U1OTGIR<3>) interrupt), the A-device must restore the VBUS supply by either setting VBUSON (U1OTGCON<3>) or by setting the I/O port controlling the external power source.

The B-device should not monitor the state of the VBUS supply while performing VBUS supply pulsing. When the B-device does detect that the VBUS supply has been restored (via the SESVDIF (U1OTGIR<3>) interrupt), the B-device must reconnect to the USB link by pulling up D+ or D- (via the DPPULUP or DMPULUP bits).

The A-device must complete the SRP by driving USB Reset signaling.

## 19.6.2 HOST NEGOTIATION PROTOCOL (HNP)

In USB OTG applications, a Dual Role Device (DRD) is a device that is capable of being either a host or a peripheral. Any OTG DRD must support Host Negotiation Protocol (HNP).

HNP allows an OTG B-device to temporarily become the USB host. The A-device must first enable the B-device to follow HNP. Refer to the “*On-The-Go Supplement*” to the “*USB 2.0 Specification*” for more information regarding HNP. HNP may only be initiated at full speed.

After being enabled for HNP by the A-device, the B-device requests being the host any time that the USB link is in suspend state by simply indicating a disconnect. This can be done in software by clearing DPPULUP and DMPULUP. When the A-device detects the disconnect condition (via the URSTIF (U1IR<0>) interrupt), the A-device may allow the B-device to take over as host. The A-device does this by signaling connect as a full-speed function. Software may accomplish this by setting DPPULUP.

If the A-device responds instead with resume signaling, the A-device remains as host. When the B-device detects the connect condition (via ATTACHIF), the B-device becomes host. The B-device drives Reset signaling prior to using the bus.

When the B-device has finished in its role as host, it stops all bus activity and turns on its D+ pull-up resistor by setting DPPULUP. When the A-device detects a suspend condition (Idle for 3 ms), the A-device turns off its D+ pull-up. The A-device may also power down the VBUS supply to end the session. When the A-device detects the connect condition (via ATTACHIF), the A-device resumes host operation and drives Reset signaling.

## 19.7 USB OTG Module Registers

There are a total of 37 memory-mapped registers associated with the USB OTG module. They can be divided into four general categories:

- USB OTG Module Control (12)
- USB Interrupt (7)
- USB Endpoint Management (16)
- USB VBUS Power Control (2)

This total does not include the (up to) 128 BD registers in the BDT. Their prototypes, described in [Register 19-1](#) and [Register 19-2](#), are shown separately in [Section 19.2 “USB Buffer Descriptors and the BDT”](#).

All USB OTG registers are implemented in the Least Significant Byte of the register. Bits in the upper byte are unimplemented and have no function. Note that some registers are instantiated only in Host mode, while other registers have different bit instantiations and functions in Device and Host modes.

The registers described in the following sections are those that have bits with specific control and configuration features. The following registers are used for data or address values only:

- U1BDTP1: Specifies the 256-word page in data RAM used for the BDT; 8-bit value with bit 0 fixed as ‘0’ for boundary alignment.
- U1FRML and U1FRMH: Contain the 11-bit byte counter for the current data frame.

**NOTES:**

## 20.0 DATA SIGNAL MODULATOR (DSM)

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Data Signal Modulator (DSM)” (DS39744). The information in this data sheet supersedes the information in the FRM.

The Data Signal Modulator (DSM) allows the user to mix a digital data stream (the “modulator signal”) with a carrier signal to produce a modulated output. Both the carrier and the modulator signals are supplied to the DSM module, either internally from the output of a peripheral, or externally through an input pin.

The modulated output signal is generated by performing a logical AND operation of both the carrier and modulator signals, and then it is provided to the MDOUT pin. Using this method, the DSM can generate the following types of key modulation schemes:

- Frequency Shift Keying (FSK)
- Phase-Shift Keying (PSK)
- On-Off Keying (OOK)

Figure 20-1 shows a simplified block diagram of the Data Signal Modulator peripheral.

**FIGURE 20-1: SIMPLIFIED BLOCK DIAGRAM OF THE DATA SIGNAL MODULATOR**

## 21.0 ENHANCED PARALLEL MASTER PORT (EPMP)

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “*dsPIC33/PIC24 Family Reference Manual*”, “**Enhanced Parallel Master Port (EPMP)**” (DS39730). The information in this data sheet supersedes the information in the FRM.

The Enhanced Parallel Master Port (EPMP) module provides a parallel, 4-bit (Master mode only) and 8-bit (Master and Slave modes) data bus interface to communicate with off-chip modules, such as memories, FIFOs, LCD controllers and other microcontrollers. This module can serve as either the master or the slave on the communication bus.

For EPMP Master modes, all external addresses are mapped into the internal Extended Data Space (EDS). This is done by allocating a region of the EDS for each chip select and then assigning each chip select to a particular external resource, such as a memory or external controller. This region should not be assigned to another device resource, such as RAM or SFRs. To perform a write or read on an external resource, the CPU simply performs a write or read within the address range assigned for the EPMP.

Key features of the EPMP module are:

- Extended Data Space (EDS) Interface allows Direct Access from the CPU
- Up to 10 Programmable Address Lines
- Up to 2 Chip Select Lines
- Up to 1 Acknowledgment Line (one per chip select)
- 4-Bit and 8-Bit Wide Data Bus
- Programmable Strobe Options (per chip select)
  - Individual Read and Write Strobes or;
  - Read/Write Strobe with Enable Strobe
- Programmable Address/Data Multiplexing
- Programmable Address Wait States
- Programmable Data Wait States (per chip select)
- Programmable Polarity on Control Signals (per chip select)
- Legacy Parallel Slave Port (PSP) Support
- Enhanced Parallel Slave Port Support
  - Address Support
  - 4-Byte Deep Auto-Incrementing Buffer

### 21.1 Memory Addressable in Different Modes

The memory space addressable by the device depends on the address/data multiplexing selection; it varies from 1K to 2 MB. Refer to [Table 21-1](#) for different Memory-Addressable modes.

# PIC24FJ128GB204 FAMILY

## 22.0 REAL-TIME CLOCK AND CALENDAR (RTCC)

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information on the Real-Time Clock and Calendar, refer to the “dsPIC33/PIC24 Family Reference Manual”, “RTCC with External Power Control” (DS39745).

The RTCC provides the user with a Real-Time Clock and Calendar (RTCC) function that can be calibrated.

Key features of the RTCC module are:

- Operates in Deep Sleep mode
- Selectable clock source
- Provides hours, minutes and seconds using 24-hour format
- Visibility of one half second period
- Provides calendar – weekday, date, month and year
- Alarm-configurable for half a second, one second, 10 seconds, one minute, 10 minutes, one hour, one day, one week, one month or one year
- Alarm repeat with decrementing counter
- Alarm with indefinite repeat chime
- Year 2000 to 2099 leap year correction

- BCD format for smaller software overhead
- Optimized for long-term battery operation
- User calibration of the 32.768 kHz clock crystal/32K INTRC frequency with periodic auto-adjust
- Optimized for long-term battery operation
- Fractional second synchronization
- Calibration to within  $\pm 2.64$  seconds error per month
- Calibrates up to 260 ppm of crystal error
- Ability to periodically wake up external devices without CPU intervention (external power control)
- Power control output for external circuit control
- Calibration takes effect every 15 seconds
- Runs from any one of the following:
  - External Real-Time Clock (RTC) of 32.768 kHz
  - Internal 31.25 kHz LPRC clock
  - 50 Hz or 60 Hz external input

### 22.1 RTCC Source Clock

The user can select between the SOSC crystal oscillator, LPRC internal oscillator or an external 50 Hz/60 Hz power line input as the clock reference for the RTCC module. This gives the user an option to trade off system cost, accuracy and power consumption, based on the overall system needs.

**FIGURE 22-1: RTCC BLOCK DIAGRAM**

# PIC24FJ128GB204 FAMILY

## 22.2 RTCC Module Registers

The RTCC module registers are organized into three categories:

- RTCC Control Registers
- RTCC Value Registers
- Alarm Value Registers

### 22.2.1 REGISTER MAPPING

To limit the register interface, the RTCC Timer and Alarm Time registers are accessed through corresponding register pointers. The RTCC Value register window (RTCVALH and RTCVALL) uses the RTCPTRx bits (RCFGCAL<9:8>) to select the desired Timer register pair (see [Table 22-1](#)).

By writing the RTCVALH byte, the RTCPTR<1:0> bits (the RTCC Pointer value) decrement by one until they reach '00'. Once they reach '00', the MINUTES and SECONDS value will be accessible through RTCVALH and RTCVALL until the pointer value is manually changed.

**TABLE 22-1: RTCVAL REGISTER MAPPING**

RTCPTR<1:0>	RTCC Value Register Window	
	RTCVAL<15:8>	RTCVAL<7:0>
00	MINUTES	SECONDS
01	WEEKDAY	HOURS
10	MONTH	DAY
11	—	YEAR

The Alarm Value register window (ALRMVALH and ALRMVALL) uses the ALRMPTRx bits (ALCGRPT<9:8>) to select the desired Alarm register pair (see [Table 22-2](#)).

By writing the ALRMVALH byte, the ALRMPTR<1:0> bits (the Alarm Pointer value) decrement by one until they reach '00'. Once they reach '00', the ALRMMIN and ALRMSEC value will be accessible through ALRMVALH and ALRMVALL until the pointer value is manually changed.

**TABLE 22-2: ALRMVAL REGISTER MAPPING**

ALRMPTR <1:0>	Alarm Value Register Window	
	ALRMVAL<15:8>	ALRMVAL<7:0>
00	ALRMMIN	ALRMSEC
01	ALRMWD	ALRMHR
10	ALRMMNTH	ALRMDAY
11	—	—

Considering that the 16-bit core does not distinguish between 8-bit and 16-bit read operations, the user must be aware that when reading either the ALRMVALH or ALRMVALL bytes, the ALRMPTR<1:0> value will be decremented. The same applies to the RTCVALH or RTCVALL bytes with the RTCPTR<1:0> being decremented.

**Note:** This only applies to read operations and not write operations.

### 22.2.2 WRITE LOCK

In order to perform a write to any of the RTCC Timer registers, the RTCWREN bit (RCFGCAL<13>) must be set (see [Example 22-1](#)).

**Note:** To avoid accidental writes to the timer, it is recommended that the RTCWREN bit (RCFGCAL<13>) is kept clear at any other time. For the RTCWREN bit to be set, there is only one instruction cycle time window allowed between the 55h/AA sequence and the setting of RTCWREN; therefore, it is recommended that code follow the procedure in [Example 22-1](#).

### 22.2.3 SELECTING RTCC CLOCK SOURCE

The clock source for the RTCC module can be selected using the RTCLK<1:0> bits in the RTCPWC register. When the bits are set to '00', the Secondary Oscillator (SOSC) is used as the reference clock and when the bits are '01', LPRC is used as the reference clock. When RTCLK<1:0> = 10 and 11, the external power line (50 Hz and 60 Hz) is used as the clock source.

### EXAMPLE 22-1: SETTING THE RTCWREN BIT

```
asm volatile("push w7");
asm volatile("push w8");
asm volatile("disi #5");
asm volatile("mov #0x55, w7");
asm volatile("mov w7, _NVMKEY");
asm volatile("mov #0xAA, w8");
asm volatile("mov w8, _NVMKEY");
asm volatile("bset _RCFGCAL, #13"); //set the RTCWREN bit
asm volatile("pop w8");
asm volatile("pop w7");
```

**2:** The sample window always starts when the stability window timer expires, except when its initial value is 00h.

# PIC24FJ128GB204 FAMILY

## 22.4 Calibration

The real-time crystal input can be calibrated using the periodic auto-adjust feature. When properly calibrated, the RTCC can provide an error of less than 3 seconds per month. This is accomplished by finding the number of error clock pulses and storing the value into the lower half of the RCFGCAL register. The 8-bit signed value loaded into the lower half of RCFGCAL is multiplied by four and will either be added or subtracted from the RTCC timer, once every minute. Refer to the steps below for RTCC calibration:

1. Using another timer resource on the device, the user must find the error of the 32.768 kHz crystal.
2. Once the error is known, it must be converted to the number of error clock pulses per minute.
3. a) If the oscillator is faster than ideal (negative result from Step 2), the RCFGCAL register value must be negative. This causes the specified number of clock pulses to be subtracted from the timer counter, once every minute.  
b) If the oscillator is slower than ideal (positive result from Step 2), the RCFGCAL register value must be positive. This causes the specified number of clock pulses to be subtracted from the timer counter, once every minute.

### EQUATION 22-1:

$$\begin{aligned}(\text{Ideal Frequency} \dagger - \text{Measured Frequency}) * 60 = \\ \text{Clocks per Minute} \\ \dagger \text{ Ideal Frequency} = 32,768 \text{ Hz}\end{aligned}$$

Writes to the lower half of the RCFGCAL register should only occur when the timer is turned off, or immediately after the rising edge of the seconds pulse, except when SECONDS = 00, 15, 30 or 45. This is due to the auto-adjust of the RTCC at 15 second intervals.

**Note:** It is up to the user to include, in the error value, the initial error of the crystal: drift due to temperature and drift due to crystal aging.

## 22.5 Alarm

- Configurable from half second to one year
- Enabled using the ALRMEN bit (ALCFGRPT<15>)
- One-time alarm and repeat alarm options available

### 22.5.1 CONFIGURING THE ALARM

The alarm feature is enabled using the ALRMEN bit. This bit is cleared when an alarm is issued. Writes to ALRMVAL should only take place when ALRMEN = 0.

As shown in [Figure 22-2](#), the interval selection of the alarm is configured through the AMASKx bits (ALCFGRPT<13:10>). These bits determine which and how many digits of the alarm must match the clock value for the alarm to occur.

The alarm can also be configured to repeat based on a preconfigured interval. The amount of times this occurs, once the alarm is enabled, is stored in the ARPT<7:0> bits (ALCFGRPT<7:0>). When the value of the ARPTx bits equals 00h and the CHIME bit (ALCFGRPT<14>) is cleared, the repeat function is disabled and only a single alarm will occur. The alarm can be repeated, up to 255 times, by loading ARPT<7:0> with FFh.

After each alarm is issued, the value of the ARPTx bits is decremented by one. Once the value has reached 00h, the alarm will be issued one last time, after which, the ALRMEN bit will be cleared automatically and the alarm will turn off.

Indefinite repetition of the alarm can occur if the CHIME bit = 1. Instead of the alarm being disabled when the value of the ARPTx bits reaches 00h, it rolls over to FFh and continues counting indefinitely while CHIME is set.

### 22.5.2 ALARM INTERRUPT

At every alarm event, an interrupt is generated. In addition, an alarm pulse output is provided that operates at half the frequency of the alarm. This output is completely synchronous to the RTCC clock and can be used as a trigger clock to other peripherals.

**Note:** Changing any of the registers, other than the RCFGCAL and ALCFGRPT registers, and the CHIME bit while the alarm is enabled (ALRMEN = 1), can result in a false alarm event leading to a false alarm interrupt. To avoid a false alarm event, the timer and alarm values should only be changed while the alarm is disabled (ALRMEN = 0). It is recommended that the ALCFGRPT register and CHIME bit be changed when RTCSYNC = 0.

1001 - Every year <sup>(1)</sup>	<input type="checkbox"/>	m m	/ d d	h h	: m m	: s s

Note 1: Annually, except when configured for February 29.

## 22.6 Power Control

The RTCC includes a power control feature that allows the device to periodically wake-up an external device, wait for the device to be stable before sampling wake-up events from that device and then shut down the external device. This can be done completely autonomously by the RTCC, without the need to wake from the current lower power mode (Sleep, Deep Sleep, etc.).

To use this feature:

1. Enable the RTCC (RTCEN = 1).
2. Set the PWCEN bit (RTCPWC<15>).
3. Configure the RTCC pin to drive the PWC control signal (RTCOE = 1 and RTCOUT<1:0> = 11).

The polarity of the PWC control signal may be chosen using the PWCPOL bit (RTCPWC<14>). An active-low or active-high signal may be used with the appropriate external switch to turn on or off the power to one or

more external devices. The active-low setting may also be used in conjunction with an open-drain setting on the RTCC pin, in order to drive the ground pin(s) of the external device directly (with the appropriate external VDD pull-up device), without the need for external switches. Finally, the CHIME bit should be set to enable the PWC periodicity.

## 22.7 RTCC VBAT Operation

The RTCC can operate in VBAT mode when there is a power loss on the VDD pin. The RTCC will continue to operate if the VBAT pin is powered on (it is usually connected to the battery).

**Note:** It is recommended to connect the VBAT pin to VDD if the VBAT mode is not used (not connected to the battery).

**NOTES:**

## 23.0 CRYPTOGRAPHIC ENGINE

**Note:** This data sheet summarizes the features of the PIC24FJ128GB204 family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Cryptographic Engine” (DS70005133), which is available from the Microchip web site ([www.microchip.com](http://www.microchip.com)).

The Cryptographic Engine provides a new set of data security options. Using its own free-standing state machines, the engine can independently perform NIS standard encryption and decryption of data independently of the CPU. This eliminates the concerns of excessive CPU or program memory overhead that encryption and decryption would otherwise require, while enhancing the application’s security.

The primary features of the Cryptographic Engine are:

- Memory-mapped 128-bit and 256-bit memory spaces for encryption/decryption data
- Multiple options for key storage, selection and management

- Support for internal context saving
- Session key encryption and loading
- Half-duplex operation
- DES and Triple DES (3DES) encryption and decryption (64-bit block size):
  - Supports 64-bit keys and 2-key or 3-key Triple DES
- AES encryption and decryption (128-bit block size):
  - Supports key sizes of 128, 192 or 256 bits
- Supports ECB, CBC, CFB, OFB and CTR modes for both DES and AES standards
- Programmatically secure key storage:
  - 512-bit OTP array for key storage, not readable from other memory spaces
  - 32-bit Configuration Page
  - Simple in-module programming interface
  - Supports Key Encryption Key (KEK)
- Support for True and Pseudorandom Number Generation (PRNG), NIST SP800-90 compliant

A simplified block diagram of the Cryptographic Engine is shown in Figure 23-1.

**FIGURE 23-1: CRYPTOGRAPHIC ENGINE BLOCK DIAGRAM**

# PIC24FJ128GB204 FAMILY

---

## 23.1 Data Register Spaces

There are four register spaces used for cryptographic data and key storage:

- CRYXTXA
- CRYXTXB
- CRYXTXC
- CRYKEY

Although mapped into the SFR space, all of these Data Spaces are actually implemented as 128-bit or 256-bit wide arrays, rather than groups of 16-bit wide Data registers. Reads and writes to and from these arrays are automatically handled as if they were any other register in the SFR space.

CRYXTXA through CRYXTXC are 128-bit wide spaces; they are used for writing data to and reading from the Cryptographic Engine. Additionally, they are also used for storing intermediate results of the encryption/decryption operation. None of these registers may be written to when the module is performing an operation (CRYGO = 1).

CRYXTXA and CRYXTXB normally serve as inputs to the encryption/decryption process.

CRYXTXA usually contains the initial plaintext or ciphertext to be encrypted or decrypted. Depending on the mode of operation, CRYXTXB may contain the ciphertext output or intermediate cipher data. It may also function as a programmable length counter in certain operations.

CRYXTXC is primarily used to store the final output of an encryption/decryption operation. It is also used as the input register for data to be programmed to the secure OTP array.

CRYKEY is a 256-bit wide space, used to store cryptographic keys for the selected operation. It is writable from both the SFR space and the secure OTP array. Although mapped into the SFR space, it is a write-only memory area; any data placed here, regardless of its source, cannot be read back by any run-time operations. This feature helps to ensure the security of any key data.

## 23.2 Modes of Operation

The Cryptographic Engine supports the following modes of operation, determined by the OPMOD<3:0> bits:

- Block Encryption
- Block Decryption
- AES Decryption Key Expansion
- Random Number Generation
- Session Key Generation
- Session Key Encryption
- Session Key Loading

The OPMODx bits may be changed while CRYON is set. They should only be changed when a cryptographic operation is not being done (CRYGO = 0).

Once the encryption operation, and the appropriate and valid key configuration is selected, the operation is performed by setting the CRYGO bit. This bit is automatically

cleared by hardware when the operation is complete. The CRYGO bit can also be manually cleared by software; this causes any operation in progress to terminate immediately. Clearing this bit in software also sets the CRYABRT bit (CRYSTAT<5>).

For most operations, CRYGO can only be set when an OTP operation is not being performed and there are no other error conditions. CRYREAD, CRYWR, CRYABRT, ROLLOVR, MODFAIL and KEYFAIL must all be '0'.

Setting CRYWR and CRYGO simultaneously will not initiate an OTP programming operation or any other operation. Setting CRYGO when the module is disabled (CRYON = 0) also has no effect.

## 23.3 Enabling the Engine

The Cryptographic Engine is enabled by setting the CRYON bit. Clearing this bit disables both the DES and AES engines, as well as causing the following register bits to be held in Reset:

- CRYGO (CRYCONL<8>)
- TXTABSY (CRYSTAT<6>)
- CRYWR (CRYOTP<0>)

All other register bits and registers may be read and written while CRYON = 0.

## 23.4 Operation During Sleep and Idle Modes

### 23.4.1 OPERATION DURING SLEEP MODES

Whenever the device enters any Sleep or Deep Sleep mode, all operation engine state machines are reset. This feature helps to preserve the integrity, or any data being encrypted or decrypted, by discarding any intermediate text that might be used to break the key.

Any OTP programming operations under way when a Sleep mode is entered are also halted. Depending on what is being programmed, this may result in permanent loss of a memory location or potentially, the use of the entire secure OTP array. Users are advised to perform OTP programming only when entry into power-saving modes is disabled.

**Note:** OTP programming errors, regardless of the source, are not recoverable errors. Users should ensure that all foreseeable interruptions to the programming operation, including device interrupts and entry into power-saving modes, are disabled.

### 23.4.2 OPERATION DURING IDLE MODE

When the CRYSIDL bit (CRYCONL<13>) is '0', the engine will continue any ongoing operations without interruption when the device enters Idle mode.

When CRYSIDL is '1', the module behaves as in Sleep modes.

## 23.5 Specific Cryptographic Operations

This section provides the step-wise details for each operation type that is available with the Cryptographic Engine.

### 23.5.1 ENCRYPTING DATA

1. If not already set, set the CRYON bit.
2. Configure the CPHRSEL, CPHRMODx, KEYMODx and KEYSRCx bits as desired to select the proper mode and key length.
3. Set OPMOD<3:0> to '0000'.
4. If a software key is being used, write it to the CRYKEY register. It is only necessary to write the lowest  $n$  bits of CRYKEY for a key length of  $n$ , as all unused CRYKEY bits are ignored.
5. Read the KEYFAIL bit. If this bit is '1', an illegal configuration has been selected and the encrypt operation will NOT be performed.
6. Write the data to be encrypted to the appropriate CRYTXT register. For a single DES encrypt operation, it is only necessary to write the lowest 64 bits. However, for data less than the block size (64 bits for DES, 128 bits for AES), it is the responsibility of the software to properly pad the upper bits within the block.
7. Set the CRYGO bit.
8. In ECB and CBC modes, set the FREEIE bit (CRYCONL<10>) to enable the optional CRYXTA interrupt to indicate when the next plaintext block can be loaded.
9. Poll the CRYGO bit until it is cleared or wait for the CRYDNIF module interrupt (DONEIE must be set). If other Cryptographic Engine interrupts are enabled, it will be necessary to poll the CRYGO bit to verify the interrupt source.
10. Read the encrypted block from the appropriate CRYTXT register.
11. Repeat Steps 5 through 8 to encrypt further blocks in the message with the same key.

### 23.5.2 DECRYPTING DATA

1. If not already set, set the CRYON bit.
2. Configure the CPHRSEL, CPHRMODx, KEYMODx and KEYSRCx bits as desired to select the proper mode and key length.
3. Set OPMOD<3:0> to '0001'.
4. If a software key is being used, write the CRYKEY register. It is only necessary to write the lowest  $n$  bits of CRYKEY for a key length of  $n$ , as all unused CRYKEY bits are ignored.
5. If an AES-ECB or AES-CBC mode decryption is being performed, you must first perform an AES decryption key expansion operation.
6. Read the KEYFAIL status bit. If this bit is '1', an illegal configuration has been selected and the encrypt operation will not be performed.
7. Write the data to be decrypted into the appropriate text/data register. For a DES decrypt operation, it is only necessary to write the lowest 64 bits of CRYTXTB.
8. Set the CRYGO bit.
9. If this is the first decrypt operation after a Reset, or if a key storage program operation was performed after the last decrypt operation, or if the KEYMODx or KEYSRCx fields are changed, the engine will perform a new key expansion operation. This will result in extra clock cycles for the decrypt operation, but will otherwise be transparent to the application (i.e., the CRYGO bit will be cleared only after the key expansion and the decrypt operation have completed).
10. In ECB and CBC modes, set the FREEIE bit (CRYCONL<10>) to enable the optional CRYXTA interrupt to indicate when the next plaintext block can be loaded.
11. Poll the CRYGO bit until it is cleared or wait for the CRYDNIF module interrupt (DONEIE must be set). If other Cryptographic Engine interrupts are enabled, it will be necessary to poll the CRYGO bit to verify the interrupt source.
12. Read the decrypted block out of the appropriate text/data register.
13. Repeat Steps 6 through 10 to encrypt further blocks in the message with the same key.

# PIC24FJ128GB204 FAMILY

---

## 23.5.3 ENCRYPTING A SESSION KEY

**Note:** ECB and CBC modes are restricted to 128-bit session keys only.

1. If not already set, set the CRYON bit.
2. If not already programmed, program the SKEYEN bit to '1'.

**Note:** Setting SKEYEN permanently makes Key #1 available as a Key Encryption Key only. It cannot be used for other encryption or decryption operations after that.
3. Set OPMOD<3:0> to '1110'.
4. Configure the CPHRSEL, CPHRMOD<2:0> and KEYMOD<1:0> register bit fields as desired, set SKEYSEL to '0'.
5. Read the KEYFAIL status bit. If this bit is '1', an illegal configuration has been selected, and the encrypt operation will not be performed.
6. Write the software generated session key into the CRYKEY register or generate a random key into the CRYKEY register. It is only necessary to write the lowest  $n$  bits of CRYKEY for a key length of  $n$ , as all unused key bits are ignored.
7. Set the CRYGO bit. Poll the bit until it is cleared by hardware; alternatively, set the DONEIE bit (CRYCONL<11>) to generate an interrupt when the encryption is done.
8. Read the encrypted session key out of the appropriate CRYTXT register.
9. For total key lengths of more than 128 bits, set SKEYSEL to '1' and repeat Steps 6 and 7.
10. Set KEYSRC<3:0> to '0000' to use the session key to encrypt data.

## 23.5.4 RECEIVING A SESSION KEY

**Note:** ECB and CBC modes are restricted to 128-bit session keys only.

1. If not already set, set the CRYON bit.
2. If not already programmed, program the SKEYEN bit to '1'.

**Note:** Setting SKEYEN permanently makes Key #1 available as a Key Encryption Key only. It cannot be used for other encryption or decryption operations after that. It also permanently disables the ability of software to decrypt the session key into the CRYXTA register, thereby breaking programmatic security (i.e., software can read the unencrypted key).

3. Set OPMOD<3:0> to '1111'.
4. Configure the CPHRSEL, CPHRMOD<2:0> and KEYMOD<1:0> register bit fields as desired, set SKEYSEL to '0'.
5. Read the KEYFAIL status bit. If this bit is '1', an illegal configuration has been selected and the encrypt operation will NOT be performed.
6. Write the encrypted session key received into the appropriate CRYTXT register.
7. Set the CRYGO bit. Poll the bit until it is cleared by hardware; alternatively, set the DONEIE bit (CRYCONL<11>) to generate an interrupt when the process is done.
8. For total key lengths of more than 128 bits, set SKEYSEL to '1' and repeat Steps 6 and 7.
9. Set KEYSRC<3:0> to '0000' to use the newly generated session key to encrypt and decrypt data.

## 23.5.5 GENERATING A PSEUDORANDOM NUMBER (PRN)

For operations that require a Pseudorandom Number (PRN), the method outlined in NIST SP800-90 can be adapted for efficient use with the Cryptographic Engine. This method uses the AES algorithm in CTR mode to create PRNs with minimal CPU overhead. PRNs generated in this manner can be used for cryptographic purposes or any other purpose that the host application may require.

The random numbers used as initial seeds can be taken from any source convenient to the user's application. If possible, a non-deterministic random number source should be used.

**Note:** PRN generation is not available when software keys are disabled (SWKYDIS = 1).

To perform the initial reseeding operation, and subsequent reseedings after the reseeding interval has expired:

1. Store a random number (128 bits) in CRYTXTA.
2. For the initial generation ONLY, use a key value of 0h (128 bits), and a counter value of 0h.
3. Configure the engine for AES encryption, CTR mode (OPMOD<3:0> = 0000, CPHRSEL = 1, CPHMOD<2:0> = 100).
4. Perform an encrypt operation by setting CRYGO.
5. Move the results in CRYTXTC to RAM. This is the new key value (NEW\_KEY).
6. Store another random number (128 bits) in CRYTXTA.
7. Configure the module for encryption as in Step 3.
8. Perform an encrypt operation by setting CRYGO.
9. Store this value in RAM. This is the new counter value (NEW\_CTR).
10. For subsequent reseeding operations, use NEW\_KEY and NEW\_CTR for the starting key and counter values.

To generate the pseudorandom number:

1. Load NEW\_KEY value from RAM into CRYKEY.
2. Load NEW\_CTR value from RAM into CRYXTXB.
3. Load CRYTXTA with 0h (128 bits).
4. Configure the engine for AES encryption, CTR mode (OPMOD<3:0> = 0000, CPHRSEL = 1, CPHMOD<2:0> = 100).
5. Perform an encrypt operation by setting CRYGO.
6. Copy the generated PRN in CRYTXTC (PRNG\_VALUE) to RAM.
7. Repeat the encrypt operation.
8. Store the value of CRYTXTC from this round as the new value of NEW\_KEY.
9. Repeat the encrypt operation.
10. Store the value of CRYTXTC from this round as the new value of NEW\_CTR.

Subsequent PRNs can be generated by repeating this procedure until the reseeding interval has expired. At that point, the reseeding operation is performed using the stored values of NEW\_KEY and NEW\_CTR.

## 23.5.6 GENERATING A RANDOM NUMBER

1. Enable the Cryptographic mode (CRYON (CRYCONL<15>) = 1).
2. Set the OPMOD<3:0> bits to '1010'.
3. Start the request by setting the CRYGO bit (CRYCONL<8>) to '1'.
4. Wait for the CRYGO bit to be cleared to '0' by the hardware.
5. Read the random number from the CRYTXTA register.

## 23.5.7 TESTING THE KEY SOURCE CONFIGURATION

The validity of the key source configuration can always be tested by writing the appropriate register bits and then reading the KEYFAIL register bit. No operation needs to be started to perform this check; the module does not even need to be enabled.

# PIC24FJ128GB204 FAMILY

## 23.5.8 PROGRAMMING CFGPAGE (PAGE 0) CONFIGURATION BITS

1. If not already set, set the CRYON bit. Set KEYPG<3:0> to '0000'.
2. Read the PGMFAIL status bit. If this bit is '1', an illegal configuration has been selected and the programming operation will not be performed.
3. Write the data to be programmed into the Configuration Page into CRYTXTC<31:0>. Any bits that are set ('1') will be permanently programmed, while any bits that are cleared ('0') will not be programmed and may be programmed at a later time.
4. Set the CRYWR bit. Poll the bit until it is cleared; alternatively, set the OTPIE bit (CRYOTP<6>) to enable the optional OTP done interrupt.
5. Once all programming has completed, set the CRYREAD bit to reload the values from the on-chip storage. A read operation must be performed to complete programming.

**Note:** Do not clear the CRYON bit while the CRYREAD bit is set; this will result in an incomplete read operation and unavailable key data. To recover, set CRYON and CRYREAD, and allow the read operation to fully complete.

6. Poll the CRYREAD bit until it is cleared; alternatively, set the OTPIE bit (CRYOTP<6>) to enable the optional OTP done interrupt.
7. For production programming, the TSTPGM bit can be set to indicate a successful programming operation. When TSTPGM is set, the PGMTST bit (CRYOTP<7>) will also be set, allowing users to see the OTP array status with performing a read operation on the array.

**Note:** If the device enters Sleep mode during OTP programming, the contents of the OTP array may become corrupted. This is not a recoverable error. Users must ensure that entry into power-saving modes is disabled before OTP programming is performed.

## 23.5.9 PROGRAMMING KEYS

1. If not already set, set the CRYON bit.
2. Configure KEYPG<3:0> to the page you want to program.
3. Read the PGMFAIL status bit. If this bit is '1', an illegal configuration has been selected and the programming operation will not be performed.
4. Write the data to be programmed into the Configuration Page into CRYTXTC<63:0>. Any bits that are set ('1') will be permanently programmed, while any bits that are cleared ('0') will not be programmed and may be programmed at a later time.
5. Set the CRYWR bit. Poll the bit until it is cleared; alternatively, set the OTPIE bit (CRYOTP<6>) to enable the optional OTP done interrupt.
6. Repeat Steps 2 through 5 for each OTP array page to be programmed.
7. Once all programming has completed, set the CRYREAD bit to reload the values from the on-chip storage. A read operation must be performed to complete programming.

**Note:** Do not clear the CRYON bit while the CRYREAD bit is set; this will result in an incomplete read operation and unavailable key data. To recover, set CRYON and CRYREAD, and allow the read operation to fully complete.

8. Poll the CRYREAD bit until it is cleared; alternatively, set the OTPIE bit (CRYOTP<6>) to enable the optional OTP done interrupt.
9. For production programming, the TSTPGM bit can be set to indicate a successful programming operation. When TSTPGM is set, the PGMTST bit (CRYOTP<7>) will also be set, allowing users to see the OTP array status with performing a read operation on the array.

**Note:** If the device enters Sleep Mode during OTP programming, the contents of the OTP array may become corrupted. This is not a recoverable error. Users must ensure that entry into power-saving modes is disabled before OTP programming is performed.

## 23.5.10 VERIFYING PROGRAMMED KEYS

To maintain key security, the secure OTP array has no provision to read back its data to any user-accessible memory space in any operating mode. Therefore, there is no way to directly verify programmed data. The only method for verifying that they have been programmed correctly is to perform an encryption operation with a known plaintext/ciphertext pair for each programmed key.

## 23.6 Control Registers

### REGISTER 23-1: CRYCONL: CRYPTOGRAPHIC CONTROL LOW REGISTER

R/W-0	U-0	R/W-0	R/W-0 <sup>(1)</sup>	R/W-0 <sup>(1)</sup>	R/W-0 <sup>(1)</sup>	U-0	R/W-0, HC <sup>(1)</sup>

'1' = Bit is set

'0' = Bit is cleared

x = Bit is unknown

bit 15      **Unimplemented:** Read as '0'

bit 14-8      **CTRSIZE<6:0>:** Counter Size Select bits<sup>(1,2,3)</sup>

Counter is defined as CRYTXTB<n:0>, where n = CTRSIZEx. Counter increments after each operation and generates a rollover event when the counter rolls over from  $(2^{n-1} - 1)$  to 0.

1111111 = 128 bits (CRYTXTB<127:0>)

1111110 = 127 bits (CRYTXTB<126:0>)

•

•

0000010 = 3 bits (CRYTXTB<2:0>)

0000001 = 2 bits (CRYTXTB<1:0>)

0000000 = 1 bit (CRYTXTB<0>); rollover event occurs when CRYTXTB<0> toggles from '1' to '0'

bit 7      **SKEYSEL:** Session Key Select bit<sup>(1)</sup>

1 = Key generation/encryption/loading are performed with CRYKEY<255:128>

0 = Key generation/encryption/loading are performed with CRYKEY<127:0>

bit 6-5      **KEYMOD<1:0>:** AES/DES Encrypt/Decrypt Key Mode/Key Length Select bits<sup>(1,2)</sup>

For DES Encrypt/Decrypt Operations (CPHRSEL = 0):

11 = 64-bit, 3-key 3DES

10 = Reserved

01 = 64-bit, standard 2-key 3DES

00 = 64-bit DES

For AES Encrypt/Decrypt Operations (CPHRSEL = 1):

11 = Reserved

10 = 256-bit AES

01 = 192-bit AES

00 = 128-bit AES

bit 4      **Unimplemented:** Read as '0'

bit 3-0      **KEYSRC<3:0>:** Cipher Key Source bits<sup>(1,2)</sup>

Refer to [Table 23-1](#) and [Table 23-2](#) for KEYSRC<3:0> values.

**Note 1:** These bits are reset on system Resets or whenever the CRYMD bit is set.

**2:** Writes to these bit fields are locked out whenever an operation is in progress (CRYGO bit is set).

**3:** Used only in CTR operations when CRYTXTB is being used as a counter; otherwise, these bits have no effect.

**NOTES:**

## 24.0 32-BIT PROGRAMMABLE CYCLIC REDUNDANCY CHECK (CRC) GENERATOR

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “32-Bit Programmable Cyclic Redundancy Check (CRC)” (DS30009729). The information in this data sheet supersedes the information in the FRM.

The 32-bit programmable CRC generator provides a hardware implemented method of quickly generating checksums for various networking and security applications. It offers the following features:

- User-programmable CRC polynomial equation, up to 32 bits
- Programmable shift direction (little or big-endian)
- Independent data and polynomial lengths
- Configurable interrupt output
- Data FIFO

Figure 24-1 displays a simplified block diagram of the CRC generator. A simple version of the CRC shift engine is displayed in Figure 24-2.

**FIGURE 24-1: CRC MODULE BLOCK DIAGRAM**

**FIGURE 24-2: CRC SHIFT ENGINE DETAIL**

# PIC24FJ128GB204 FAMILY

## 24.1 User Interface

### 24.1.1 POLYNOMIAL INTERFACE

The CRC module can be programmed for CRC polynomials of up to the 32<sup>nd</sup> order, using up to 32 bits.

Polynomial length, which reflects the highest exponent in the equation, is selected by the PLEN<4:0> bits (CRCCON2<4:0>).

The CRCXORL and CRCXORH registers control which exponent terms are included in the equation. Setting a particular bit includes that exponent term in the equation. Functionally, this includes an XOR operation on the corresponding bit in the CRC engine. Clearing the bit disables the XOR.

For example, consider two CRC polynomials, one is a 16-bit and the other is a 32-bit equation.

### EQUATION 24-1: 16-BIT, 32-BIT CRC POLYNOMIALS

$$X^{16} + X^{12} + X^5 + 1$$

and

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

To program these polynomials into the CRC generator, set the register bits, as shown in [Table 24-1](#).

Note that the appropriate positions are set to '1' to indicate that they are used in the equation (for example, X<sub>26</sub> and X<sub>23</sub>). The '0' bit required by the equation is always XORed; thus, X<sub>0</sub> is a don't care. For a polynomial of length 32, it is assumed that the 32<sup>nd</sup> bit will be used. Therefore, the X<31:1> bits do not have the 32<sup>nd</sup> bit.

### 24.1.2 DATA INTERFACE

The module incorporates a FIFO that works with a variable data width. Input data width can be configured to any value between 1 and 32 bits using the DWIDTH<4:0> bits (CRCCON2<12:8>). When the data width is greater than 15, the FIFO is 4 words deep. When the DWIDTHx bits are between 15 and 8, the FIFO is 8 words deep. When the DWIDTHx bits are less than 8, the FIFO is 16 words deep.

The data for which the CRC is to be calculated must first be written into the FIFO. Even if the data width is less than 8, the smallest data element that can be written into the FIFO is 1 byte. For example, if the DWIDTHx bits are 5, then the size of the data is DWIDTH<4:0> + 1 or 6. The data is written as a whole byte; the two unused upper bits are ignored by the module.

Once data is written into the MSb of the CRCDAT registers (that is, the MSb as defined by the data width), the value of the VWORD<4:0> bits (CRCCON1<12:8>) increments by one. For example, if the DWIDTHx bits are 24, the VWORDx bits will increment when bit 7 of CRCDATH is written. Therefore, CRCDATL must always be written to before CRCDATH.

The CRC engine starts shifting data when the CRCGO bit is set and the value of the VWORDx bits is greater than zero.

Each word is copied out of the FIFO into a buffer register, which decrements the VWORDx bits. The data is then shifted out of the buffer. The CRC engine continues shifting at a rate of two bits per instruction cycle, until the VWORDx bits reach zero. This means that for a given data width, it takes half that number of instructions for each word to complete the calculation. For example, it takes 16 cycles to calculate the CRC for a single word of 32-bit data.

When the VWORDx bits reach the maximum value for the configured value of the DWIDTHx bits (4, 8 or 16), the CRCFUL bit becomes set. When the VWORDx bits reach zero, the CRCMPT bit becomes set. The FIFO is emptied and the VWORD<4:0> bits are set to '00000' whenever CRCEN is '0'.

At least one instruction cycle must pass after a write to CRCWDAT before a read of the VWORDx bits is done.

TABLE 24-1: CRC SETUP EXAMPLES FOR 16 AND 32-BIT POLYNOMIALS

CRC Control Bits	Bit Values	
	16-Bit Polynomial	32-Bit Polynomial
PLEN<4:0>	01111	11111
X<31:16>	0000 0000 0000 0001	0000 0100 1100 0001
X<15:0>	0001 0000 0010 00x	0001 1101 1011 011x

### 24.1.3 DATA SHIFT DIRECTION

The LENDIAN bit (CRCCON1<3>) is used to control the shift direction. By default, the CRC will shift data through the engine, MSb first. Setting LENDIAN (= 1) causes the CRC to shift data, LSb first. This setting allows better integration with various communication schemes and removes the overhead of reversing the bit order in software. Note that this only changes the direction the data is shifted into the engine. The result of the CRC calculation will still be a normal CRC result, not a reverse CRC result.

### 24.1.4 INTERRUPT OPERATION

The module generates an interrupt that is configurable by the user for either of two conditions.

If CRCISEL is '0', an interrupt is generated when the VWORD<4:0> bits make a transition from a value of '1' to '0'. If CRCISEL is '1', an interrupt will be generated after the CRC operation finishes and the module sets the CRCGO bit to '0'. Manually setting CRCGO to '0' will not generate an interrupt. Note that when an interrupt occurs, the CRC calculation would not yet be complete. The module will still need (PLEN + 1)/2 clock cycles, after the interrupt is generated, until the CRC calculation is finished.

### 24.1.5 TYPICAL OPERATION

To use the module for a typical CRC calculation:

1. Set the CRCEN bit to enable the module.
2. Configure the module for desired operation:
  - a) Program the desired polynomial using the CRCXORL and CRCXORH registers, and the PLEN<4:0> bits.
  - b) Configure the data width and shift direction using the DWIDTHx and LENDIAN bits.
  - c) Select the desired Interrupt mode using the CRCISEL bit.
3. Preload the FIFO by writing to the CRCDATL and CRCDATH registers until the CRCFUL bit is set or no data is left.

4. Clear old results by writing 00h to CRCWDATL and CRCWDATH. The CRCWDAT registers can also be left unchanged to resume a previously halted calculation.
5. Set the CRCGO bit to start calculation.
6. Write remaining data into the FIFO as space becomes available.
7. When the calculation completes, CRCGO is automatically cleared. An interrupt will be generated if CRCISEL = 1.
8. Read CRCWDATL and CRCWDATH for the result of the calculation.

There are eight registers used to control programmable CRC operation:

- CRCCON1
- CRCCON2
- CRCXORL
- CRCXORH
- CRCDATL
- CRCDATH
- CRCWDATL
- CRCWDATH

The CRCCON1 and CRCCON2 registers ([Register 24-1](#) and [Register 24-2](#)) control the operation of the module and configure the various settings.

The CRCXORL/H registers ([Register 24-3](#) and [Register 24-4](#)) select the polynomial terms to be used in the CRC equation. The CRCDAT and CRCWDAT registers are each register pairs that serve as buffers for the double-word input data and CRC processed output, respectively.

## 25.0 12-BIT A/D CONVERTER WITH THRESHOLD DETECT

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information on the 12-Bit A/D Converter, refer to the “dsPIC33/PIC24 Family Reference Manual”, “12-Bit A/D Converter with Threshold Detect” (DS39739).

The 12-bit A/D Converter has the following key features:

- Successive Approximation Register (SAR) Conversion
- Conversion Speeds of up to 200 kspS
- Up to 19 Analog Input Channels (internal and external)
- Selectable 10-Bit or 12-Bit (default) Conversion Resolution
- Multiple Internal Reference Input Channels
- External Voltage Reference Input Pins
- Unipolar Differential Sample-and-Hold (S/H) Amplifier
- Automated Threshold Scan and Compare Operation to Pre-Evaluate Conversion Results
- Selectable Conversion Trigger Source
- Fixed Length (one word per channel), Configurable Conversion Result Buffer
- Four Options for Results Alignment
- Configurable Interrupt Generation
- Enhanced DMA Operations with Indirect Address Generation
- Operation During CPU Sleep and Idle modes

The 12-bit A/D Converter module is an enhanced version of the 10-bit module offered in earlier PIC24 devices. It is a Successive Approximation Register (SAR) Converter, enhanced with 12-bit resolution, a wide range of automatic sampling options, tighter integration with other analog modules and a configurable results buffer.

It also includes a unique Threshold Detect feature that allows the module itself to make simple decisions based on the conversion results, and enhanced operation with the DMA Controller through Peripheral Indirect Addressing (PIA).

A simplified block diagram for the module is shown in [Figure 25-1](#).

## 25.1 Basic Operation

To perform a standard A/D conversion:

1. Configure the module:
  - a) Configure port pins as analog inputs by setting the appropriate bits in the ANSx registers (see [Section 11.2 “Configuring Analog Port Pins \(ANSx\)”](#) for more information).
  - b) Select the voltage reference source to match the expected range on analog inputs (AD1CON2<15:13>).
  - c) Select the positive and negative multiplexer inputs for each channel (AD1CHS<15:0>).
  - d) Select the analog conversion clock to match the desired data rate with the processor clock (AD1CON3<7:0>).
  - e) Select the appropriate sample/conversion sequence (the AD1CON1<7:4> and AD1CON3<12:8> bits).
  - f) For Channel A scanning operations, select the positive channels to be included (AD1CSSH and AD1CSSL registers).
  - g) Select how the conversion results are presented in the buffer (AD1CON1<9:8> and the AD1CON5 register).
  - h) Select the interrupt rate (AD1CON2<6:2>).
  - i) Turn on A/D module (AD1CON1<15>).
2. Configure the A/D interrupt (if required):
  - a) Clear the AD1IF bit (IFS0<13>).
  - b) Enable the AD1IE interrupt (IEC0<13>).
  - c) Select the A/D interrupt priority (IPC3<6:4>).
3. If the module is configured for manual sampling, set the SAMP bit (AD1CON1<1>) to begin sampling.

# PIC24FJ128GB204 FAMILY

**FIGURE 25-1: 12-BIT A/D CONVERTER BLOCK DIAGRAM (PIC24FJ128GB204 FAMILY)**

## 25.2 Extended DMA Operations

In addition to the standard features available on all 12-bit A/D Converters, PIC24FJ128GB204 family devices implement a limited extension of DMA functionality. This extension adds features that work with the device's DMA Controller to expand the A/D module's data storage abilities beyond the module's built-in buffer.

The Extended DMA functionality is controlled by the DMAEN bit (AD1CON1<11>); setting this bit enables the functionality. The DMABM bit (AD1CON1<12>) configures how the DMA feature operates.

### 25.2.1 EXTENDED BUFFER MODE

Extended Buffer mode (DMABM = 1) is useful for storing the results of channels. It can also be used to store the conversion results on any A/D channel in any implemented address in data RAM.

In Extended Buffer mode, all data from the A/D Buffer register, and channels above 26, are mapped into data RAM. Conversion data is written to a destination specified by the DMA Controller, specifically by the DMADSTn register. This allows users to read the conversion results of channels above 26, which do not have their own memory-mapped A/D buffer locations, from data memory.

When using Extended Buffer mode, always set the BUFREGEN bit to disable FIFO operation. In addition, disable the Split Buffer mode by clearing the BUFM bit.

### 25.2.2 PIA MODE

When DMABM = 0, the A/D module is configured to function with the DMA Controller for Peripheral Indirect Addressing (PIA) mode operations. In this mode, the A/D module generates an 11-bit Indirect Address (IA). This is ORed with the destination address in the DMA Controller to define where the A/D conversion data will be stored.

In PIA mode, the buffer space is created as a series of contiguous smaller buffers, one per analog channel. The size of the channel buffer determines how many analog channels can be accommodated. The size of the buffer is selected by the DMABLx bits (AD1CON4<2:0>). The size options range from a single word per buffer to 128 words. Each channel is allocated a buffer of this size, regardless of whether or not the channel will actually have conversion data.

The IA is created by combining the base address within a channel buffer with three to five bits (depending on the buffer size) to identify the channel. The base address ranges from zero to seven bits wide, depending on the buffer size. The address is right-padded with a '0' in order to maintain address alignment in the Data Space. The concatenated channel and base address bits are then left-padded with zeros, as necessary, to complete the 11-bit IA.

The IA is configured to auto-increment during write operations by using the SMP1x bits (AD1CON2<6:2>).

As with PIA operations for any DMA-enabled module, the base destination address in the DMADSTn register must be masked properly to accommodate the IA. [Table 25-1](#) shows how complete addresses are formed. Note that the address masking varies for each buffer size option. Because of masking requirements, some address ranges may not be available for certain buffer sizes. Users should verify that the DMA base address is compatible with the buffer size selected.

[Figure 25-2](#) shows how the parts of the address define the buffer locations in data memory. In this case, the module "allocates" 256 bytes of data RAM (1000h to 1100h) for 32 buffers of four words each. However, this is not a hard allocation and nothing prevents these locations from being used for other purposes. For example, in the current case, if Analog Channels 1, 3 and 8 are being sampled and converted, conversion data will only be written to the channel buffers, starting at 1008h, 1018h and 1040h. The holes in the PIA buffer space can be used for any other purpose. It is the user's responsibility to keep track of buffer locations and preventing data overwrites.

## 25.3 A/D Operation with VBAT

One of the A/D channels is connected to the VBAT pin to monitor the VBAT voltage. This allows monitoring the VBAT pin voltage (battery voltage) with no external connection. The voltage measured, using the A/D VBAT monitor, is VBAT/2. The voltage can be calculated by reading A/D = ((VBAT/2)/VDD) \* 1024 for 10-bit A/D and ((VBAT/2)/VDD) \* 4096 for 12 bit A/D.

When using the VBAT A/D monitor:

- Connect the A/D channel to ground to discharge the sample capacitor.
- Because of the high-impedance of VBAT, select higher sampling time to get an accurate reading.

Since the VBAT pin is connected to the A/D during sampling, to prolong the VBAT battery life, the recommendation is to only select the VBAT channel when needed.

## 25.4 Registers

The 12-bit A/D Converter is controlled through a total of 11 registers:

- AD1CON1 through AD1CON5 ([Register 25-1](#) through [Register 25-5](#))
- AD1CHS ([Register 25-6](#))
- AD1CHITL ([Register 25-8](#))
- AD1CSSH and AD1CSSL ([Register 25-9](#) and [Register 25-10](#))
- AD1CTMENL ([Register 25-11](#))
- AD1DMBUF (not shown) – The 16-bit conversion buffer for Extended Buffer mode

TABLE 25-1: INDIRECT ADDRESS GENERATION IN PIA MODE

DMABL<2:0>	Buffer Size per Channel (words)	Generated Offset Address (lower 11 bits)	Available Input Channels	Allowable DMADSTn Addresses
000	1	000 00cc ccc0	32	xxxx xxxx xx00 0000

## 26.0 TRIPLE COMPARATOR MODULE

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Scalable Comparator Module” (DS39734). The information in this data sheet supersedes the information in the FRM.

The triple comparator module provides three dual input comparators. The inputs to the comparator can be configured to use any one of five external analog inputs (CxINA, CxINB, CxINC, CxIND and VREF+) and a

voltage reference input from one of the internal band gap references or the comparator voltage reference generator (VBG, VBG/2 and CVREF).

The comparator outputs may be directly connected to the CxOUT pins. When the respective COE equals ‘1’, the I/O pad logic makes the unsynchronized output of the comparator available on the pin.

A simplified block diagram of the module is shown in Figure 26-1. Diagrams of the possible individual comparator configurations are shown in Figure 26-2, Figure 26-3 and Figure 26-4.

Each comparator has its own control register, CMxCON (Register 26-1), for enabling and configuring its operation. The output and event status of all three comparators is provided in the CMSTAT register (Register 26-2).

**NOTES:**

## 27.0 COMPARATOR VOLTAGE REFERENCE

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Comparator Voltage Reference Module” (DS39709). The information in this data sheet supersedes the information in the FRM.

## 27.1 Configuring the Comparator Voltage Reference

The comparator voltage reference module is controlled through the CVRCON register ([Register 27-1](#)). The comparator voltage reference provides a range of output voltages with 32 distinct levels. The comparator reference supply voltage can come from either VDD and VSS, or the external CVREF+ and CVREF- pins. The voltage source is selected by the CVRSS bit (CVRCON<5>).

The settling time of the comparator voltage reference must be considered when changing the CVREF output.

## 28.0 CHARGE TIME MEASUREMENT UNIT (CTMU)

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information on the Charge Time Measurement Unit, refer to the “*dsPIC33/PIC24 Family Reference Manual*”, “**Charge Time Measurement Unit (CTMU) with Threshold Detect**” (DS39743). The information in this data sheet supersedes the information in the FRM.

The Charge Time Measurement Unit (CTMU) is a flexible analog module that provides charge measurement, accurate differential time measurement between pulse sources and asynchronous pulse generation. Its key features include:

- Thirteen external edge input trigger sources
- Polarity control for each edge source
- Control of edge sequence
- Control of response to edge levels or edge transitions
- Time measurement resolution of one nanosecond
- Accurate current source suitable for capacitive measurement

Together with other on-chip analog modules, the CTMU can be used to precisely measure time, measure capacitance, measure relative changes in capacitance or generate output pulses that are independent of the system clock. The CTMU module is ideal for interfacing with capacitive-based touch sensors.

The CTMU is controlled through three registers: CTMUCON1, CTMUCON2 and CTMUICON. CTMUCON1 enables the module and controls the mode of operation of the CTMU, as well as controlling edge sequencing. CTMUCON2 controls edge source selection and edge source polarity selection. The CTMUICON register selects the current range of the current source and trims the current.

## 28.1 Measuring Capacitance

The CTMU module measures capacitance by generating an output pulse, with a width equal to the time between edge events, on two separate input channels. The pulse edge events to both input channels can be selected from four sources: two internal peripheral modules (OC1 and Timer1) and up to 13 external pins (CTED1 through CTED13). This pulse is used with the module's precision current source to calculate capacitance according to the relationship:

### EQUATION 28-1:

$$I = C \cdot \frac{dV}{dT}$$

For capacitance measurements, the A/D Converter samples an external Capacitor (CAPP) on one of its input channels after the CTMU output's pulse. A Precision Resistor (RPR) provides current source calibration on a second A/D channel. After the pulse ends, the converter determines the voltage on the capacitor. The actual calculation of capacitance is performed in software by the application.

[Figure 28-1](#) illustrates the external connections used for capacitance measurements and how the CTMU and A/D modules are related in this application. This example also shows the edge events coming from Timer1, but other configurations using external edge sources are possible. A detailed discussion on measuring capacitance and time with the CTMU module is provided in the “*dsPIC33/PIC24 Family Reference Manual*”, “**Charge Time Measurement Unit (CTMU) with Threshold Detect**” (DS39743).

# PIC24FJ128GB204 FAMILY

FIGURE 28-1: TYPICAL CONNECTIONS AND INTERNAL CONFIGURATION FOR CAPACITANCE MEASUREMENT

## 28.2 Measuring Time

Time measurements on the pulse width can be similarly performed using the A/D module's Internal Capacitor (CAD) and a precision resistor for current calibration. [Figure 28-2](#) displays the external connections used for time measurements, and how the CTMU and A/D modules are related in this application. This example also shows both edge events coming from the external CTED pins, but other configurations using internal edge sources are possible.

## 28.3 Pulse Generation and Delay

The CTMU module can also generate an output pulse with edges that are not synchronous with the device's system clock. More specifically, it can generate a pulse with a programmable delay from an edge event input to the module.

When the module is configured for pulse generation delay by setting the TGEN bit (CTMUCON1<12>), the internal current source is connected to the B input of Comparator 2. A Capacitor (CDELAY) is connected to the Comparator 2 pin, C2INB, and the Comparator voltage Reference, CVREF, is connected to C2INA. CVREF is then configured for a specific trip point. The module begins to charge CDELAY when an edge event is detected. When CDELAY charges above the CVREF trip point, a pulse is output on CTPLS. The length of the pulse delay is determined by the value of CDELAY and the CVREF trip point.

[Figure 28-3](#) illustrates the external connections for pulse generation, as well as the relationship of the different analog modules required. While CTED1 is shown as the input pulse source, other options are available. A detailed discussion on pulse generation with the CTMU module is provided in the “*dsPIC33/PIC24 Family Reference Manual*”.

**NOTES:**

## 29.0 HIGH/LOW-VOLTAGE DETECT (HLVD)

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information on the High/Low-Voltage Detect, refer to the “dsPIC33/PIC24 Family Reference Manual”, “High-Level Integration with Programmable High/Low-Voltage Detect (HLVD)” (DS39725).

An interrupt flag is set if the device experiences an excursion past the trip point in the direction of change. If the interrupt is enabled, the program execution will branch to the interrupt vector address and the software can then respond to the interrupt.

The HLVD Control register (see [Register 29-1](#)) completely controls the operation of the HLVD module. This allows the circuitry to be “turned off” by the user under software control, which minimizes the current consumption for the device.

The High/Low-Voltage Detect (HLVD) module is a programmable circuit that allows the user to specify both the device voltage trip point and the direction of change.

## 30.0 SPECIAL FEATURES

**Note:** This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the following sections of the “*dsPIC33/PIC24 Family Reference Manual*”. The information in this data sheet supersedes the information in the FRMs.

- “**Watchdog Timer (WDT)**”  
(DS39697)
- “**High-Level Device Integration**”  
(DS39719)
- “**Programming and Diagnostics**”  
(DS39716)

PIC24FJ128GB204 family devices include several features intended to maximize application flexibility and reliability, and minimize cost through elimination of external components. These are:

- Flexible Configuration
- Watchdog Timer (WDT)
- Code Protection
- JTAG Boundary Scan Interface
- In-Circuit Serial Programming™ (ICSP™)
- In-Circuit Emulation (ICE)

### 30.1 Configuration Bits

The Configuration bits can be programmed (read as ‘0’), or left unprogrammed (read as ‘1’), to select various device configurations. These bits are mapped starting at program memory location, F80000h. A detailed explanation of the various bit functions is provided in [Register 30-1](#) through [Register 30-6](#).

Note that address, F80000h, is beyond the user program memory space. In fact, it belongs to the configuration memory space (800000h-FFFFFh), which can only be accessed using Table Reads and Table Writes.

### 30.1.1 CONSIDERATIONS FOR CONFIGURING PIC24FJ128GB204 FAMILY DEVICES

In PIC24FJ128GB204 family devices, the Configuration bytes are implemented as volatile memory. This means that configuration data must be programmed each time the device is powered up. Configuration data is stored in the four words at the top of the on-chip program memory space, known as the Flash Configuration Words. Their specific locations are shown in [Table 30-1](#). These are packed representations of the actual device Configuration bits, whose actual locations are distributed among several locations in configuration space. The configuration data is automatically loaded from the Flash Configuration Words to the proper Configuration registers during device Resets.

**Note:** Configuration data is reloaded on all types of device Resets.

When creating applications for these devices, users should always specifically allocate the location of the Flash Configuration Word for configuration data. This is to make certain that program code is not stored in this address when the code is compiled.

The upper byte of all Flash Configuration Words in program memory should always be: ‘0000 0000’. This makes them appear to be NOP instructions in the remote event that their locations are ever executed by accident. Since Configuration bits are not implemented in the corresponding locations, writing ‘0’s to these locations has no effect on device operation.

**Note:** Performing a page erase operation on the last page of program memory clears the Flash Configuration Words, enabling code protection as a result. Therefore, users should avoid performing page erase operations on the last page of program memory.

**TABLE 30-1: FLASH CONFIGURATION WORD LOCATIONS FOR THE PIC24FJ128GB204 FAMILY**

## 30.2 On-Chip Voltage Regulator

All PIC24FJ128GB204 family devices power their core digital logic at a nominal 1.8V. This may create an issue for designs that are required to operate at a higher typical voltage, such as 3.3V. To simplify system design, all devices in the PIC24FJ128GB204 family incorporate an on-chip regulator that allows the device to run its core logic from VDD.

This regulator is always enabled. It provides a constant voltage (1.8V nominal) to the digital core logic, from a VDD of about 2.1V, all the way up to the device's VDDMAX. It does not have the capability to boost VDD levels. In order to prevent "brown-out" conditions when the voltage drops too low for the regulator, the Brown-out Reset occurs. Then, the regulator output follows VDD with a typical voltage drop of 300 mV.

A low-ESR capacitor (such as ceramic) must be connected to the VCAP pin (Figure 30-1). This helps to maintain the stability of the regulator. The recommended value for the filter capacitor (CEFC) is provided in [Section 33.1 "DC Characteristics"](#).

**FIGURE 30-1: CONNECTIONS FOR THE ON-CHIP REGULATOR**

### 30.2.1 ON-CHIP REGULATOR AND POR

The voltage regulator requires a small amount of time to transition from a disabled or standby state into normal operating mode. During this time, designated as TVREG, code execution is disabled. TVREG is applied every time the device resumes operation after any power-down, including Sleep mode. TVREG is determined by the status of the VREGS bit (RCON<8>). Refer to [Section 33.0 "Electrical Characteristics"](#) for more information on TVREG.

**Note:** For more information, see [Section 33.0 "Electrical Characteristics"](#). The information in this data sheet supersedes the information in the "dsPIC33/PIC24 Family Reference Manual".

### 30.2.2 VOLTAGE REGULATOR STANDBY MODE

The on-chip regulator always consumes a small incremental amount of current over IDD/IPD, including when the device is in Sleep mode, even though the core digital logic does not require power. To provide additional savings in applications where power resources are critical, the regulator can be made to enter Standby mode on its own, whenever the device goes into Sleep mode. This feature is controlled by the VREGS bit (RCON<8>). Clearing the VREGS bit enables the Standby mode. When waking up from Standby mode, the regulator needs to wait for TVREG to expire before wake-up.

### 30.2.3 LOW-VOLTAGE/RETENTION REGULATOR

When a power-saving mode, such as Sleep is used, PIC24FJ128GB204 family devices may use a separate low-power, low-voltage/retention regulator to power critical circuits. This regulator, which operates at 1.2V nominal, maintains power to data RAM and the RTCC while all other core digital logic is powered down. It operates only in Sleep and VBAT modes.

The low-voltage/retention regulator is described in more detail in [Section 10.1.3 "Low-Voltage/Retention Regulator"](#).

# PIC24FJ128GB204 FAMILY

## 30.3 Watchdog Timer (WDT)

For PIC24FJ128GB204 family devices, the WDT is driven by the LPRC Oscillator. When the WDT is enabled, the clock source is also enabled.

The nominal WDT clock source from LPRC is 31 kHz. This feeds a prescaler that can be configured for either 5-bit (divide-by-32) or 7-bit (divide-by-128) operation. The prescaler is set by the FWPSA Configuration bit. With a 31 kHz input, the prescaler yields a nominal WDT Time-out (TWDT) period of 1 ms in 5-bit mode or 4 ms in 7-bit mode.

A variable postscaler divides down the WDT prescaler output and allows for a wide range of time-out periods. The postscaler is controlled by the WDTPS<3:0> Configuration bits (CW1<3:0>), which allows the selection of a total of 16 settings, from 1:1 to 1:32,768. Using the prescaler and postscaler time-out periods, ranges from 1 ms to 131 seconds can be achieved.

The WDT, prescaler and postscaler are reset:

- On any device Reset
- On the completion of a clock switch, whether invoked by software (i.e., setting the OSWEN bit after changing the NOSCx bits) or by hardware (i.e., Fail-Safe Clock Monitor)
- When a PWRSAV instruction is executed (i.e., Sleep or Idle mode is entered)
- When the device exits Sleep or Idle mode to resume normal operation
- By a CLRWDT instruction during normal execution

If the WDT is enabled, it will continue to run during Sleep or Idle modes. When the WDT time-out occurs, the device will wake the device and code execution will continue from where the PWRSAV instruction was executed. The corresponding SLEEP or IDLE (RCON<3:2>) bits will need to be cleared in software after the device wakes up.

The WDT Flag bit, WDTO (RCON<4>), is not automatically cleared following a WDT time-out. To detect subsequent WDT events, the flag must be cleared in software.

**Note:** The CLRWDT and PWRSAV instructions clear the prescaler and postscaler counts when executed.

### 30.3.1 WINDOWED OPERATION

The Watchdog Timer has an optional Fixed Window mode of operation. In this Windowed mode, CLRWDT instructions can only reset the WDT during the window width, 25%, 37.5%, 50% or 75% of the programmed WDT period, controlled by the WDTWIN<1:0> Configuration bits (CW3<10:9>). A CLRWDT instruction executed before that window causes a WDT Reset, similar to a WDT time-out.

Windowed WDT mode is enabled by programming the WNDIS Configuration bit (CW1<5>) to '0'.

### 30.3.2 CONTROL REGISTER

The WDT is enabled or disabled by the FWDTEN<1:0> Configuration bits. When the Configuration bits, FWDTEN<1:0> = 11, the WDT is always enabled.

The WDT can be optionally controlled in software when the Configuration bits, FWDTEN<1:0> = 10. When FWDTEN<1:0> = 00, the Watchdog Timer is always disabled. The WDT is enabled in software by setting the SWDTEN control bit (RCON<5>). The SWDTEN control bit is cleared on any device Reset. The software WDT option allows the user to enable the WDT for critical code segments and disable the WDT during non-critical segments for maximum power savings.

**FIGURE 30-2: WDT BLOCK DIAGRAM**

## 30.4 Program Verification and Code Protection

PIC24FJ128GB204 family devices provide two complementary methods to protect application code from overwrites and erasures. These also help to protect the device from inadvertent configuration changes during run time.

### 30.4.1 GENERAL SEGMENT PROTECTION

For all devices in the PIC24FJ128GB204 family, the on-chip program memory space is treated as a single block, known as the General Segment (GS). Code protection for this block is controlled by one Configuration bit, GCP. This bit inhibits external reads and writes to the program memory space. It has no direct effect in normal execution mode.

Write protection is controlled by the GWRP bit in Configuration Word 1. When GWRP is programmed to '0', internal write and erase operations to program memory are blocked.

### 30.4.2 CODE SEGMENT PROTECTION

In addition to global General Segment protection, a separate subrange of the program memory space can be individually protected against writes and erases. This area can be used for many purposes where a separate block of write and erase-protected code is needed, such as bootloader applications. Unlike common boot block implementations, the specially protected segment in the PIC24FJ128GB204 family devices can be located by the user anywhere in the program space and configured in a wide range of sizes.

Code Segment (CS) protection provides an added level of protection to a designated area of program memory by disabling the NVM safety interlock whenever a write or erase address falls within a specified range. It does not override General Segment protection controlled by the GCP or GWRP bits. For example, if GCP and GWRP are enabled, enabling segmented code protection for the bottom half of program memory does not undo General Segment protection for the top half.

The size and type of protection for the segmented code range are configured by the WPFPx, WPEND, WPCFG and WPDIS bits in Configuration Word 3. Code Segment protection is enabled by programming the WPDIS bit (= 0). The WPFPx bits specify the size of the segment to be protected, by specifying the 512-word code page that is the start or end of the protected segment. The specified region is inclusive, therefore, this page will also be protected.

The WPEND bit determines if the protected segment uses the top or bottom of the program space as a boundary. Programming WPEND (= 0) sets the bottom of program memory (000000h) as the lower boundary of the protected segment. Leaving WPEND unprogrammed (= 1) protects the specified page through the last page of implemented program memory, including the Configuration Word locations.

A separate bit, WPCFG, is used to protect the last page of program space, including the Flash Configuration Words. Programming WPCFG (= 0) protects the last page in addition to the pages selected by the WPEND and WPFP<6:0> bits setting. This is useful in circumstances where write protection is needed for both the Code Segment in the bottom of the memory and the Flash Configuration Words.

The various options for segment code protection are shown in [Table 30-2](#).

**TABLE 30-2: CODE SEGMENT PROTECTION CONFIGURATION OPTIONS**

Segment Configuration Bits			Write/Erase Protection of Code Segment
WPDIS	WPEND	WPCFG	
1	x	x	No additional protection is enabled; all program memory protection is configured by GCP and GWRP.
0	1	x	Addresses from the first address of the code page are defined by WPFP<6:0> through the end of implemented program memory (inclusive); erase/write-protected, including Flash Configuration Words.
0	0	1	Address, 000000h through the last address of the code page, is defined by WPFP<6:0> (inclusive); erase/write-protected.
0	0	0	Address, 000000h through the last address of the code page, is defined by WPFP<6:0> (inclusive); erase/write-protected and the last page, including the Flash Configuration Words, are erase/write-protected.

# PIC24FJ128GB204 FAMILY

---

## 30.4.3 CONFIGURATION REGISTER PROTECTION

The Configuration registers are protected against inadvertent or unwanted changes or reads in two ways. The primary protection method is the same as that of the RP registers – shadow registers contain a complementary value which is constantly compared with the actual value.

To safeguard against unpredictable events, Configuration bit changes, resulting from individual cell-level disruptions (such as ESD events), will cause a parity error and trigger a device Reset.

The data for the Configuration registers is derived from the Flash Configuration Words in program memory. When the GCP bit is set, the source data for device configuration is also protected as a consequence. Even if General Segment protection is not enabled, the device configuration can be protected by using the appropriate Code Segment protection setting.

## 30.5 JTAG Interface

PIC24FJ128GB204 family devices implement a JTAG interface, which supports boundary scan device testing and programming.

## 30.6 In-Circuit Serial Programming

PIC24FJ128GB204 family microcontrollers can be serially programmed while in the end application circuit. This is simply done with two lines for clock (PGECx) and data (PGEDx), and three other lines for power (VDD), ground (Vss) and MCLR. This allows customers to manufacture boards with unprogrammed devices and then program the microcontroller just before shipping the product. This also allows the most recent firmware or a custom firmware to be programmed.

## 30.7 In-Circuit Debugger

When MPLAB® ICD 3 is selected as a debugger, the in-circuit debugging functionality is enabled. This function allows simple debugging functions when used with MPLAB X IDE. Debugging functionality is controlled through the PGECx (Emulation/Debug Clock) and PGEDx (Emulation/Debug Data) pins.

To use the in-circuit debugger function of the device, the design must implement ICSP connections to MCLR, VDD, Vss and the PGECx/PGEDx pin pair, designated by the ICSx Configuration bits. In addition, when the feature is enabled, some of the resources are not available for general use. These resources include the first 80 bytes of data RAM and two I/O pins.

## 31.0 DEVELOPMENT SUPPORT

The PIC® microcontrollers (MCU) and dsPIC® digital signal controllers (DSC) are supported with a full range of software and hardware development tools:

- Integrated Development Environment
  - MPLAB® X IDE Software
- Compilers/Assemblers/Linkers
  - MPLAB XC Compiler
  - MPASM™ Assembler
  - MPLINK™ Object Linker/  
MPLIB™ Object Librarian
  - MPLAB Assembler/Linker/Librarian for  
Various Device Families
- Simulators
  - MPLAB X SIM Software Simulator
- Emulators
  - MPLAB REAL ICE™ In-Circuit Emulator
- In-Circuit Debuggers/Programmers
  - MPLAB ICD 3
  - PICkit™ 3
- Device Programmers
  - MPLAB PM3 Device Programmer
- Low-Cost Demonstration/Development Boards,  
Evaluation Kits and Starter Kits
- Third-party development tools

## 31.1 MPLAB X Integrated Development Environment Software

The MPLAB X IDE is a single, unified graphical user interface for Microchip and third-party software, and hardware development tool that runs on Windows®, Linux and Mac OS® X. Based on the NetBeans IDE, MPLAB X IDE is an entirely new IDE with a host of free software components and plug-ins for high-performance application development and debugging. Moving between tools and upgrading from software simulators to hardware debugging and programming tools is simple with the seamless user interface.

With complete project management, visual call graphs, a configurable watch window and a feature-rich editor that includes code completion and context menus, MPLAB X IDE is flexible and friendly enough for new users. With the ability to support multiple tools on multiple projects with simultaneous debugging, MPLAB X IDE is also suitable for the needs of experienced users.

### Feature-Rich Editor:

- Color syntax highlighting
- Smart code completion makes suggestions and provides hints as you type
- Automatic code formatting based on user-defined rules
- Live parsing

### User-Friendly, Customizable Interface:

- Fully customizable interface: toolbars, toolbar buttons, windows, window placement, etc.
- Call graph window

### Project-Based Workspaces:

- Multiple projects
- Multiple tools
- Multiple configurations
- Simultaneous debugging sessions

### File History and Bug Tracking:

- Local file history feature
- Built-in support for Bugzilla issue tracker

# PIC24FJ128GB204 FAMILY

---

## 31.2 MPLAB XC Compilers

The MPLAB XC Compilers are complete ANSI C compilers for all of Microchip's 8, 16, and 32-bit MCU and DSC devices. These compilers provide powerful integration capabilities, superior code optimization and ease of use. MPLAB XC Compilers run on Windows, Linux or MAC OS X.

For easy source level debugging, the compilers provide debug information that is optimized to the MPLAB X IDE.

The free MPLAB XC Compiler editions support all devices and commands, with no time or memory restrictions, and offer sufficient code optimization for most applications.

MPLAB XC Compilers include an assembler, linker and utilities. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. MPLAB XC Compiler uses the assembler to produce its object file. Notable features of the assembler include:

- Support for the entire device instruction set
- Support for fixed-point and floating-point data
- Command-line interface
- Rich directive set
- Flexible macro language
- MPLAB X IDE compatibility

## 31.3 MPASM Assembler

The MPASM Assembler is a full-featured, universal macro assembler for PIC10/12/16/18 MCUs.

The MPASM Assembler generates relocatable object files for the MPLINK Object Linker, Intel® standard HEX files, MAP files to detail memory usage and symbol reference, absolute LST files that contain source lines and generated machine code, and COFF files for debugging.

The MPASM Assembler features include:

- Integration into MPLAB X IDE projects
- User-defined macros to streamline assembly code
- Conditional assembly for multipurpose source files
- Directives that allow complete control over the assembly process

## 31.4 MPLINK Object Linker/ MPLIB Object Librarian

The MPLINK Object Linker combines relocatable objects created by the MPASM Assembler. It can link relocatable objects from precompiled libraries, using directives from a linker script.

The MPLIB Object Librarian manages the creation and modification of library files of precompiled code. When a routine from a library is called from a source file, only the modules that contain that routine will be linked in with the application. This allows large libraries to be used efficiently in many different applications.

The object linker/library features include:

- Efficient linking of single libraries instead of many smaller files
- Enhanced code maintainability by grouping related modules together
- Flexible creation of libraries with easy module listing, replacement, deletion and extraction

## 31.5 MPLAB Assembler, Linker and Librarian for Various Device Families

MPLAB Assembler produces relocatable machine code from symbolic assembly language for PIC24, PIC32 and dsPIC DSC devices. MPLAB XC Compiler uses the assembler to produce its object file. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. Notable features of the assembler include:

- Support for the entire device instruction set
- Support for fixed-point and floating-point data
- Command-line interface
- Rich directive set
- Flexible macro language
- MPLAB X IDE compatibility

## 31.6 MPLAB X SIM Software Simulator

The MPLAB X SIM Software Simulator allows code development in a PC-hosted environment by simulating the PIC MCUs and dsPIC DSCs on an instruction level. On any given instruction, the data areas can be examined or modified and stimuli can be applied from a comprehensive stimulus controller. Registers can be logged to files for further run-time analysis. The trace buffer and logic analyzer display extend the power of the simulator to record and track program execution, actions on I/O, most peripherals and internal registers.

The MPLAB X SIM Software Simulator fully supports symbolic debugging using the MPLAB XC Compilers, and the MPASM and MPLAB Assemblers. The software simulator offers the flexibility to develop and debug code outside of the hardware laboratory environment, making it an excellent, economical software development tool.

## 31.7 MPLAB REAL ICE In-Circuit Emulator System

The MPLAB REAL ICE In-Circuit Emulator System is Microchip's next generation high-speed emulator for Microchip Flash DSC and MCU devices. It debugs and programs all 8, 16 and 32-bit MCU, and DSC devices with the easy-to-use, powerful graphical user interface of the MPLAB X IDE.

The emulator is connected to the design engineer's PC using a high-speed USB 2.0 interface and is connected to the target with either a connector compatible with in-circuit debugger systems (RJ-11) or with the new high-speed, noise tolerant, Low-Voltage Differential Signal (LVDS) interconnection (CAT5).

The emulator is field upgradable through future firmware downloads in MPLAB X IDE. MPLAB REAL ICE offers significant advantages over competitive emulators including full-speed emulation, run-time variable watches, trace analysis, complex breakpoints, logic probes, a ruggedized probe interface and long (up to three meters) interconnection cables.

## 31.8 MPLAB ICD 3 In-Circuit Debugger System

The MPLAB ICD 3 In-Circuit Debugger System is Microchip's most cost-effective, high-speed hardware debugger/programmer for Microchip Flash DSC and MCU devices. It debugs and programs PIC Flash microcontrollers and dsPIC DSCs with the powerful, yet easy-to-use graphical user interface of the MPLAB X IDE.

The MPLAB ICD 3 In-Circuit Debugger probe is connected to the design engineer's PC using a high-speed USB 2.0 interface and is connected to the target with a connector compatible with the MPLAB ICD 2 or MPLAB REAL ICE systems (RJ-11). MPLAB ICD 3 supports all MPLAB ICD 2 headers.

## 31.9 PICkit 3 In-Circuit Debugger/Programmer

The MPLAB PICkit 3 allows debugging and programming of PIC and dsPIC Flash microcontrollers at a most affordable price point using the powerful graphical user interface of the MPLAB X IDE. The MPLAB PICkit 3 is connected to the design engineer's PC using a full-speed USB interface and can be connected to the target via a Microchip debug (RJ-11) connector (compatible with MPLAB ICD 3 and MPLAB REAL ICE). The connector uses two device I/O pins and the Reset line to implement in-circuit debugging and In-Circuit Serial Programming™ (ICSP™).

## 31.10 MPLAB PM3 Device Programmer

The MPLAB PM3 Device Programmer is a universal, CE compliant device programmer with programmable voltage verification at VDDMIN and VDDMAX for maximum reliability. It features a large LCD display (128 x 64) for menus and error messages, and a modular, detachable socket assembly to support various package types. The ICSP cable assembly is included as a standard item. In Stand-Alone mode, the MPLAB PM3 Device Programmer can read, verify and program PIC devices without a PC connection. It can also set code protection in this mode. The MPLAB PM3 connects to the host PC via an RS-232 or USB cable. The MPLAB PM3 has high-speed communications and optimized algorithms for quick programming of large memory devices, and incorporates an MMC card for file storage and data applications.

---

## 31.11 Demonstration/Development Boards, Evaluation Kits, and Starter Kits

A wide variety of demonstration, development and evaluation boards for various PIC MCUs and dsPIC DSCs allows quick application development on fully functional systems. Most boards include prototyping areas for adding custom circuitry and provide application firmware and source code for examination and modification.

The boards support a variety of features, including LEDs, temperature sensors, switches, speakers, RS-232 interfaces, LCD displays, potentiometers and additional EEPROM memory.

The demonstration and development boards can be used in teaching environments, for prototyping custom circuits and for learning about various microcontroller applications.

In addition to the PICDEM™ and dsPICDEM™ demonstration/development board series of circuits, Microchip has a line of evaluation kits and demonstration software for analog filter design, KEELOQ® security ICs, CAN, IrDA®, PowerSmart battery management, SEEVAL® evaluation system, Sigma-Delta ADC, flow rate sensing, plus many more.

Also available are starter kits that contain everything needed to experience the specified device. This usually includes a single application and debug capability, all on one board.

Check the Microchip web page ([www.microchip.com](http://www.microchip.com)) for the complete list of demonstration, development and evaluation kits.

## 31.12 Third-Party Development Tools

Microchip also offers a great collection of tools from third-party vendors. These tools are carefully selected to offer good value and unique functionality.

- Device Programmers and Gang Programmers from companies, such as SoftLog and CCS
- Software Tools from companies, such as Gimpel and Trace Systems
- Protocol Analyzers from companies, such as Saleae and Total Phase
- Demonstration Boards from companies, such as MikroElektronika, Digilent® and Olimex
- Embedded Ethernet Solutions from companies, such as EZ Web Lynx, WIZnet and IPLogika®

## 32.0 INSTRUCTION SET SUMMARY

**Note:** This chapter is a brief summary of the PIC24F Instruction Set Architecture (ISA) and is not intended to be a comprehensive reference source.

The PIC24F instruction set adds many enhancements to the previous PIC® MCU instruction sets, while maintaining an easy migration from previous PIC MCU instruction sets. Most instructions are a single program memory word. Only three instructions require two program memory locations.

Each single-word instruction is a 24-bit word divided into an 8-bit opcode, which specifies the instruction type and one or more operands, which further specify the operation of the instruction. The instruction set is highly orthogonal and is grouped into four basic categories:

- Word or byte-oriented operations
- Bit-oriented operations
- Literal operations
- Control operations

**Table 32-1** shows the general symbols used in describing the instructions. The PIC24F instruction set summary in **Table 32-2** lists all the instructions, along with the status flags affected by each instruction.

Most word or byte-oriented W register instructions (including barrel shift instructions) have three operands:

- The first source operand, which is typically a register, 'Wb', without any address modifier
- The second source operand, which is typically a register, 'Ws', with or without an address modifier
- The destination of the result, which is typically a register, 'Wd', with or without an address modifier

However, word or byte-oriented file register instructions have two operands:

- The file register specified by the value, 'f'
- The destination, which could either be the file register, 'f', or the W0 register, which is denoted as 'WREG'

Most bit-oriented instructions (including simple rotate-shift instructions) have two operands:

- The W register (with or without an address modifier) or file register (specified by the value of 'Ws' or 'f')
- The bit in the W register or file register (specified by a literal value or indirectly by the contents of register, 'Wb')

The literal instructions that involve data movement may use some of the following operands:

- A literal value to be loaded into a W register or file register (specified by the value of 'k')
- The W register or file register where the literal value is to be loaded (specified by 'Wb' or 'f')

However, literal instructions that involve arithmetic or logical operations use some of the following operands:

- The first source operand, which is a register, 'Wb', without any address modifier
- The second source operand, which is a literal value
- The destination of the result (only if not the same as the first source operand), which is typically a register, 'Wd', with or without an address modifier

The control instructions may use some of the following operands:

- A program memory address
- The mode of the Table Read and Table Write instructions

All instructions are a single word, except for certain double-word instructions, which were made double-word instructions so that all the required information is available in these 48 bits. In the second word, the 8 MSbs are '0's. If this second word is executed as an instruction (by itself), it will execute as a NOP.

Most single-word instructions are executed in a single instruction cycle, unless a conditional test is true or the Program Counter is changed as a result of the instruction. In these cases, the execution takes two instruction cycles, with the additional instruction cycle(s) executed as a NOP. Notable exceptions are the BRA (unconditional/computed branch), indirect CALL/GOTO, all Table Reads and Table Writes, and RETURN/RETFIE instructions, which are single-word instructions but take two or three cycles.

Certain instructions that involve skipping over the subsequent instruction require either two or three cycles if the skip is performed, depending on whether the instruction being skipped is a single-word or two-word instruction. Moreover, double-word moves require two cycles. The double-word instructions execute in two instruction cycles.

**TABLE 32-1: SYMBOLS USED IN OPCODE DESCRIPTIONS**

Field	Description
#text	Means literal defined by "text"
(text)	Means "content of text"
<text>	Means "the location addressed by text"
{ }	Optional field or operation
<n:m>	Register bit field
.b	Byte mode selection
.d	Double-Word mode selection
.S	Shadow register select
.w	Word mode selection (default)
bit4	4-bit Bit Selection field (used in word addressed instructions) $\in \{0\dots15\}$
C, DC, N, OV, Z	MCU Status bits: Carry, Digit Carry, Negative, Overflow, Sticky Zero
Expr	Absolute address, label or expression (resolved by the linker)
f	File register address $\in \{0000h\dots1FFFh\}$
lit1	1-bit unsigned literal $\in \{0,1\}$
lit4	4-bit unsigned literal $\in \{0\dots15\}$
lit5	5-bit unsigned literal $\in \{0\dots31\}$
lit8	8-bit unsigned literal $\in \{0\dots255\}$
lit10	10-bit unsigned literal $\in \{0\dots255\}$ for Byte mode, $\{0:1023\}$ for Word mode
lit14	14-bit unsigned literal $\in \{0\dots16383\}$
lit16	16-bit unsigned literal $\in \{0\dots65535\}$
lit23	23-bit unsigned literal $\in \{0\dots8388607\}$ ; LSB must be '0'
None	Field does not require an entry, may be blank
PC	Program Counter
Slit10	10-bit signed literal $\in \{-512\dots511\}$
Slit16	16-bit signed literal $\in \{-32768\dots32767\}$
Slit6	6-bit signed literal $\in \{-16\dots16\}$
Wb	Base W register $\in \{W0..W15\}$
Wd	Destination W register $\in \{ Wd, [Wd], [Wd++], [Wd--], [+Wd], [-Wd] \}$
Wdo	Destination W register $\in \{ Wnd, [Wnd], [Wnd++], [Wnd--], [+Wnd], [-Wnd], [Wnd+Wb] \}$
Wm,Wn	Dividend, Divisor Working register pair (direct addressing)
Wn	One of 16 Working registers $\in \{W0..W15\}$
Wnd	One of 16 Destination Working registers $\in \{W0..W15\}$
Wns	One of 16 Source Working registers $\in \{W0..W15\}$
WREG	W0 (Working register used in file register instructions)
Ws	Source W register $\in \{ Ws, [Ws], [Ws++], [Ws--], [+Ws], [-Ws] \}$
Wso	Source W register $\in \{ Wns, [Wns], [Wns++], [Wns--], [+Wns], [-Wns], [Wns+Wb] \}$

**NOTES:**

## 33.0 ELECTRICAL CHARACTERISTICS

This section provides an overview of the PIC24FJ128GB204 family electrical characteristics. Additional information will be provided in future revisions of this document as it becomes available.

Absolute maximum ratings for the PIC24FJ128GB204 family are listed below. Exposure to these maximum rating conditions for extended periods may affect device reliability. Functional operation of the device at these, or any other conditions above the parameters indicated in the operation listings of this specification, is not implied.

### Absolute Maximum Ratings<sup>(†)</sup>

Ambient temperature under bias .....	-40°C to +100°C
Storage temperature .....	-65°C to +150°C
Voltage on VDD with respect to Vss .....	-0.3V to +4.0V
Voltage on any general purpose digital or analog pin (not 5.5V tolerant) with respect to Vss .....	-0.3V to (VDD + 0.3V)
Voltage on any general purpose digital or analog pin (5.5V tolerant, including MCLR) with respect to Vss:	
When VDD = 0V: .....	-0.3V to +4.0V
When VDD ≥ 2.0V: .....	-0.3V to +6.0V
Voltage on AVDD with respect to Vss .....	(VDD - 0.3V) to (lesser of: 4.0V or (VDD + 0.3V))
Voltage on AVss with respect to Vss .....	-0.3V to +0.3V
Voltage on VBAT with respect to Vss .....	-0.3V to +4.0V
Voltage on VUSB3V3 with respect to Vss .....	(VCAP - 0.3V) to +4.0V
Voltage on VBUS with respect to Vss .....	-0.3V to +6.0V
Voltage on D+ or D- with respect to Vss:	
0Ω source impedance ( <b>Note 1</b> ) .....	-0.5V to (VUSB3V3 + 0.5V)
Source Impedance ≥ 28Ω, VUSB3V3 ≥ 3.0V .....	-1.0V to +4.6V
Maximum current out of Vss pin .....	300 mA
Maximum current into VDD pin ( <b>Note 2</b> ) .....	250 mA
Maximum output current sunk by any I/O pin .....	25 mA
Maximum output current sourced by any I/O pin .....	25 mA
Maximum current sunk by all ports .....	200 mA
Maximum current sourced by all ports ( <b>Note 2</b> ) .....	200 mA

**Note 1:** The original USB 2.0 Specifications indicated that USB devices should withstand 24-hour short circuits of D+ or D- to VBUS voltages. This requirement was later removed in an Engineering Change Notice (ECN) supplement to the USB Specifications, which supersedes the original specifications. PIC24FJ128GB204 family devices will typically be able to survive this short-circuit test, but it is recommended to adhere to the absolute maximum specified here to avoid damaging the device.

**2:** Maximum allowable current is a function of device maximum power dissipation (see [Table 33-1](#)).

<sup>†</sup> **NOTICE:** Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

# PIC24FJ128GB204 FAMILY

## 33.1 DC Characteristics

FIGURE 33-1: PIC24FJ128GB204 FAMILY VOLTAGE-FREQUENCY GRAPH (INDUSTRIAL)

**Note 1:** Lower operating boundary is 2.0V or V<sub>BOR</sub> (when BOR is enabled), whichever is lower. For best analog performance, operation above 2.2V is suggested, but not required.

TABLE 33-1: THERMAL OPERATING CONDITIONS

Rating	Symbol	Min	Typ	Max	Unit
PIC24FJ128GB204:					
Operating Junction Temperature Range	T <sub>J</sub>	-40	—	+125	°C
Operating Ambient Temperature Range	T <sub>A</sub>	-40	—	+85	°C
Power Dissipation:					
Internal Chip Power Dissipation: P <sub>INT</sub> = V <sub>DD</sub> x (I <sub>DD</sub> - Σ I <sub>OH</sub> )	P <sub>D</sub>		P <sub>INT</sub> + P <sub>I/O</sub>		W
I/O Pin Power Dissipation: P <sub>I/O</sub> = Σ ({V <sub>DD</sub> - V <sub>OH</sub> } x I <sub>OH</sub> ) + Σ (V <sub>OL</sub> x I <sub>OL</sub> )					
Maximum Allowed Power Dissipation	P <sub>DMAX</sub>		(T <sub>J</sub> - T <sub>A</sub> )/θ <sub>JA</sub>		W

TABLE 33-2: THERMAL PACKAGING CHARACTERISTICS

Characteristic	Symbol	Typ	Max	Unit	Notes
Package Thermal Resistance, 7.50 mm 28-Pin SOIC	θ <sub>JA</sub>	49	—	°C/W	(Note 1)
Package Thermal Resistance, 6x6x0.9 mm 28-Pin QFN-S	θ <sub>JA</sub>	33.7	—	°C/W	(Note 1)
Package Thermal Resistance, 8x8 mm 44-Pin QFN	θ <sub>JA</sub>	28	—	°C/W	(Note 1)
Package Thermal Resistance, 10x10x1 mm 44-Pin TQFP	θ <sub>JA</sub>	39.3	—	°C/W	(Note 1)
Package Thermal Resistance, 5.30 mm 28-Pin SSOP	θ <sub>JA</sub>	—	—	°C/W	(Note 1)
Package Thermal Resistance, 300 mil 28-Pin SPDIP	θ <sub>JA</sub>	—	—	°C/W	(Note 1)

**Note 1:** Junction to ambient thermal resistance; Theta-JA (θ<sub>JA</sub>) numbers are achieved by package simulations.

**TABLE 33-3: DC CHARACTERISTICS: TEMPERATURE AND VOLTAGE SPECIFICATIONS**

DC CHARACTERISTICS			Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial -40°C ≤ TA ≤ +125°C for Extended				
Param No.	Symbol	Characteristic	Min	Typ	Max	Units	Conditions
<b>Operating Voltage</b>							
DC10	VDD	<b>Supply Voltage</b>	2.0	—	3.6	V	BOR disabled
			VBOR	—	3.6	V	BOR enabled
DC12	VDR	<b>RAM Data Retention Voltage<sup>(1)</sup></b>	Greater of: VPORREL or VBOR	—	—	V	VBOR used only if BOR is enabled (BOREN = 1)
DC16	VPOR	<b>VDD Start Voltage to Ensure Internal Power-on Reset Signal</b>	Vss	—	—	V	(Note 2)
DC16A	VPORREL	<b>VDD Power-on Reset Release Voltage</b>	1.80	1.88	1.95	V	(Note 3)
DC17A	SRVDD	<b>Recommended VDD Rise Rate to Ensure Internal Power-on Reset Signal</b>	0.05	—	—	V/ms	0-3.3V in 66 ms, 0-2.5V in 50 ms (Note 2)
DC17B	VBOR	<b>Brown-out Reset Voltage</b> on VDD Transition, High-to-Low	2.0	2.1	2.2	V	(Note 3)

**Note 1:** This is the limit to which VDD may be lowered and the RAM contents will always be retained.

- 2:** If the VPOR or SRVDD parameters are not met, or the application experiences slow power-down VDD ramp rates, it is recommended to enable and use BOR.
- 3:** On a rising VDD power-up sequence, application firmware execution begins at the higher of the VPORREL or VBOR level (when BOREN = 1).

## 33.2 AC Characteristics and Timing Parameters

The information contained in this section defines the PIC24FJ128GB204 family AC characteristics and timing parameters.

**TABLE 33-18: TEMPERATURE AND VOLTAGE SPECIFICATIONS – AC**

AC CHARACTERISTICS	<b>Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated)</b>
	Operating temperature $-40^{\circ}\text{C} \leq \text{TA} \leq +85^{\circ}\text{C}$ for Industrial
	$-40^{\circ}\text{C} \leq \text{TA} \leq +125^{\circ}\text{C}$ for Extended

Operating voltage VDD range as described in [Section 33.1 “DC Characteristics”](#).

**FIGURE 33-2: LOAD CONDITIONS FOR DEVICE TIMING SPECIFICATIONS**

**TABLE 33-19: CAPACITIVE LOADING REQUIREMENTS ON OUTPUT PINS**

Param No.	Symbol	Characteristic	Min	Typ <sup>(1)</sup>	Max	Units	Conditions
DO50	Cosco	OSCO/CLKO Pin	—	—	15	pF	In XT and HS modes when external clock is used to drive OSCI
DO56	CIO	All I/O Pins and OSCO	—	—	50	pF	EC mode
DO58	CB	SCLx, SDAx	—	—	400	pF	In I <sup>2</sup> C™ mode

**Note 1:** Data in the “Typ” column is at 3.3V, +25°C unless otherwise stated. Parameters are for design guidance only and are not tested.

# PIC24FJ128GB204 FAMILY

**FIGURE 33-3: EXTERNAL CLOCK TIMING**

**TABLE 33-20: EXTERNAL CLOCK TIMING REQUIREMENTS**

AC CHARACTERISTICS			Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated)				
Param No.	Symbol	Characteristic	Min	Typ <sup>(1)</sup>	Max	Units	Conditions
OS10	Fosc	External CLKI Frequency (External clocks allowed only in EC mode)	DC 4	— —	32 48	MHz MHz	EC ECPLL (Note 2)
		Oscillator Frequency	3.5 4 10 12 31	— — — — —	10 8 32 32 33	MHz MHz MHz MHz kHz	XT XTPLL HS HSPLL SOSC
OS20	Tosc	Tosc = 1/Fosc	—	—	—	—	See Parameter OS10 for Fosc value
OS25	Tcy	Instruction Cycle Time <sup>(3)</sup>	62.5	—	DC	ns	
OS30	TosL, TosH	External Clock in (OSCI) High or Low Time	0.45 x Tosc	—	—	ns	EC
OS31	TosR, TosF	External Clock in (OSCI) Rise or Fall Time	—	—	20	ns	EC
OS40	TckR	CLKO Rise Time <sup>(4)</sup>	—	6	10	ns	
OS41	TckF	CLKO Fall Time <sup>(4)</sup>	—	6	10	ns	

**Note 1:** Data in the "Typ" column is at 3.3V, +25°C unless otherwise stated. Parameters are for design guidance only and are not tested.

**2:** Represents input to the system clock prescaler. PLL dividers and postscalers must still be configured so that the system clock frequency does not exceed the maximum frequency shown in Figure 33-1.

**3:** Instruction cycle period (Tcy) equals two times the input oscillator time base period. All specified values are based on characterization data for that particular oscillator type, under standard operating conditions, with the device executing code. Exceeding these specified limits may result in an unstable oscillator operation and/or higher than expected current consumption. All devices are tested to operate at "Min." values with an external clock applied to the OSCI/CLKI pin. When an external clock input is used, the "Max." cycle time limit is "DC" (no clock) for all devices.

**4:** Measurements are taken in EC mode. The CLKO signal is measured on the OSCO pin. CLKO is low for the Q1-Q2 period (1/2 Tcy) and high for the Q3-Q4 period (1/2 Tcy).

# PIC24FJ128GB204 FAMILY

**TABLE 33-21: PLL CLOCK TIMING SPECIFICATIONS**

AC CHARACTERISTICS			Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial -40°C ≤ TA ≤ +125°C for Extended				
Param No.	Symbol	Characteristic	Min	Typ <sup>(1)</sup>	Max	Units	Conditions
OS50	FPLL1	USB PLL Input Frequency Range	2	4	4	MHz	ECPLL mode
			2	4	4	MHz	HSPLL mode
			2	4	4	MHz	XTPLL mode
OS52	TLOCK	USB PLL Start-up Time (Lock Time)	—	—	128	μs	
OS53	DCLK	CLKO Stability (Jitter)	-0.25	—	0.25	%	
OS54	F4XPLL	4x PLL Input Frequency Range	2	—	8	MHz	4xPLL
OS55	F6XPLL	6x PLL Input Frequency Range	2	—	5	MHz	6xPLL
OS56	F8XPLL	8x PLL Input Frequency Range	2	—	4	MHz	8xPLL
OS57	TxPLLLock	PLL Start-up Time (Lock Time)	—	—	24	μs	
OS58	DxPLLClock	PLL CLKO Stability (Jitter)	-2	—	2	%	

**Note 1:** These parameters are characterized but not tested in manufacturing.

**TABLE 33-22: INTERNAL RC ACCURACY**

AC CHARACTERISTICS			Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial -40°C ≤ TA ≤ +125°C for Extended				
Param No.	Characteristic	Min	Typ	Max	Units	Conditions	
F20	FRC Accuracy @ 8 MHz	-1	±0.15	1	%	2.0V ≤ VDD ≤ 3.6V, 0°C ≤ TA ≤ +85°C ( <b>Note 1</b> )	
		1.5	—	1.5	%	2.0V ≤ VDD ≤ 3.6V, -40°C ≤ TA ≤ 0°C	
		-0.20	±0.05	-0.20	%	2.0V ≤ VDD ≤ 3.6V, -40°C ≤ TA ≤ +85°C, self-tune enabled and locked ( <b>Note 2</b> )	
		—	3	5	%	2.0V ≤ VDD ≤ 3.6V, TA = +125°C	
F21	LPRC @ 31 kHz	-20	—	20	%	VCAP Output Voltage = 1.8V	
F22	OSCTUN Step-Size	—	0.05	—	%/bit		
F23	FRC Self-Tune Lock Time	—	<5	8	ms	<b>(Note 3)</b>	

**Note 1:** To achieve this accuracy, physical stress applied to the microcontroller package (ex., by flexing the PCB) must be kept to a minimum.

**2:** Accuracy is measured with respect to the reference source.

**3:** Time from reference clock stable, and in range, to FRC tuned within range specified by F20 (with self-tune).

SP31	TdoR	SDO <sub>x</sub> Data Output Rise Time <sup>(3)</sup>	—	—	—	ns	See Parameter DO31
SP35	TscH2doV, TscL2doV	SDO <sub>x</sub> Data Output Valid After SCK <sub>x</sub> Edge	—	—	30	ns	
SP40	TdiV2scH, TdiV2scL	Setup Time of SDIx Data Input to SCK <sub>x</sub> Edge	20	—	—	ns	
SP41	TscH2diL, TscL2diL	Hold Time of SDIx Data Input to SCK <sub>x</sub> Edge	20	—	—	ns	
SP50	TssL2scH, TssL2scL	SS <sub>x</sub> ↓ to SCK <sub>x</sub> ↓ or SCK <sub>x</sub> ↑ Input	120	—	—	ns	
SP51	TssH2doZ	SS <sub>x</sub> ↑ to SDO <sub>x</sub> Output High-Impedance <sup>(4)</sup>	10	—	50	ns	
SP52	TscH2ssH TscL2ssH	SS <sub>x</sub> ↑ After SCK <sub>x</sub> Edge	1.5 TCY + 40	—	—	ns	
SP60	TssL2doV	SDO <sub>x</sub> Data Output Valid After SS <sub>x</sub> Edge	—	—	50	ns	

**Note 1:** These parameters are characterized but not tested in manufacturing.

**2:** Data in "Typ" column is at 3.3V, +25°C unless otherwise stated.

**3:** The minimum clock period for SCK<sub>x</sub> is 100 ns. Therefore, the clock generated in Master mode must not violate this specification.

**4:** Assumes 50 pF load on all SPI<sub>x</sub> pins.

## 34.0 PACKAGING INFORMATION

### 34.1 Package Marking Information

28-Lead QFN-S

Example

28-Lead SOIC (.300")

Example

28-Lead SPDIP

Example

28-Lead SSOP

Example

<b>Legend:</b>	XX...X	Customer-specific information
	Y	Year code (last digit of calendar year)
	YY	Year code (last 2 digits of calendar year)
	WW	Week code (week of January 1 is week '01')
	NNN	Alphanumeric traceability code

**Note:** In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.

# PIC24FJ128GB204 FAMILY

---

## 34.1 Package Marking Information (Continued)

44-Lead QFN

Example

44-Lead TQFP

Example

# PIC24FJ128GB204 FAMILY

## 34.2 Package Details

The following sections give the technical details of the packages.

### 28-Lead Plastic Quad Flat, No Lead Package (MM) - 6x6x0.9mm Body [QFN-S] With 0.40 mm Terminal Length

**Note:** For the most current package drawings, please see the Microchip Packaging Specification located at <http://www.microchip.com/packaging>

# PIC24FJ128GB204 FAMILY

## 28-Lead Plastic Quad Flat, No Lead Package (MM) - 6x6x0.9mm Body [QFN-S] With 0.40 mm Terminal Length

**Note:** For the most current package drawings, please see the Microchip Packaging Specification located at <http://www.microchip.com/packaging>

Units		MILLIMETERS		
Dimension Limits		MIN	NOM	MAX
Number of Pins		N		28
Pitch		e		0.65 BSC

**NOTES:**

## APPENDIX A: REVISION HISTORY

### Revision A (May 2013)

Original data sheet for the PIC24FJ128GB204 family of devices.

### Revision B (May 2014)

This revision incorporates the following updates:

- Sections:
  - Inserted new bulleted list in “[Cryptographic Engine](#)”
  - Updated a unit in “[Analog Features](#)”
  - Updated note in [Section 16.0 “Serial Peripheral Interface \(SPI\)”, Section 17.0 “Inter-Integrated Circuit™ \(I<sup>2</sup>C™\)”](#), [Section 18.0 “Universal Asynchronous Receiver Transmitter \(UART\)”, Section 23.0 “Cryptographic Engine”](#) and [Section 27.0 “Comparator Voltage Reference”](#)
  - Updated [Section 17.3 “Slave Address Masking”](#)
  - Updated [Section 23.0 “Cryptographic Engine”](#)
  - Inserted new [Section 23.5.6 “Generating a Random Number”](#)
  - Updated [Section 30.3.1 “Windowed Operation”](#)
  - Updated packaging information in [Section 34.0 “Packaging Information”](#)
- Registers:
  - Updated [Register 8-45](#), [Register 16-1](#), [Register 16-4](#), [Register 17-1](#), [Register 18-1](#), [Register 20-1](#), [Register 23-1](#) and [Register 23-5](#)
  - Updated the title of [Register 18-2](#) and [Register 18-4](#)
  - Updated bit 10 register description in [Register 23-5](#)
- Tables:
  - Updated [Table 1-3](#), [Table 4-5](#), [Table 4-9](#), [Table 4-10](#), [Table 4-11](#), [Table 4-12](#), [Table 4-13](#), [Table 4-14](#), [Table 4-29](#), [Table 33-1](#), [Table 33-3](#), [Table 33-4](#), [Table 33-5](#), [Table 33-6](#), [Table 33-7](#), [Table 33-8](#), [Table 33-10](#), [Table 33-12](#), [Table 33-13](#), [Table 33-14](#), [Table 33-15](#), [Table 33-16](#), [Table 33-21](#)
  - Added [Table 33-26](#) through [Table 33-39](#)
- Figures:
  - Added [Figure 9-1](#), [Figure 33-5](#), [Figure 33-6](#), [Figure 33-7](#), [Figure 33-8](#), [Figure 33-9](#), [Figure 33-10](#), [Figure 33-11](#) and [Figure 33-12](#).
- Examples:
  - [Example 22-1](#)

### Revision C (March 2015)

This revision incorporates the following updates:

- Registers:
  - [Register 26-1](#)
- Tables:
  - [Table 33-4](#), [Table 33-5](#), [Table 33-6](#) and [Table 33-21](#)
- Package marking examples and package diagrams in [Section 34.0 “Packaging Information”](#) were updated

## INDEX

### A

#### A/D

Control Registers .....	354
Extended DMA Operations .....	353
Operation .....	351
Transfer Functions	
10-Bit .....	370
12-Bit .....	369

#### AC Characteristics

A/D Conversion Timing Requirements .....	446
A/D Specifications .....	445
and Timing Parameters .....	427
Capacitive Loading on Output Pins .....	427
CLKO and I/O Timing Requirements .....	430
External Clock Timing Requirements .....	428
I <sup>2</sup> C Bus Data (Master Mode) Requirements .....	442
I <sup>2</sup> C Bus Data (Slave Mode) Requirements .....	444
I <sup>2</sup> C Bus Start/Stop Bit Timing Requirements (Master Mode) .....	441
I <sup>2</sup> C Bus Start/Stop Bits (Slave Mode) Requirements .....	443
Input Capture x Requirements .....	434
Internal RC Accuracy .....	429
Load Conditions and Requirements for Specifications .....	427
Output Compare x Requirements .....	434
PLL Clock Timing Specifications .....	429
RC Oscillator Start-up Time .....	430
Reset and Brown-out Reset Requirements .....	431
Simple OCx/PWM Mode Requirements .....	435
SPIx Master Mode (CKE = 0) Requirements .....	436
SPIx Master Mode (CKE = 1) Requirements .....	437
SPIx Slave Mode (CKE = 0) Requirements .....	438
SPIx Slave Mode (CKE = 1) Requirements .....	440
Timer1 External Clock Requirements .....	432
Timer2 and Timer4 External Clock Requirements .....	433
Timer3 and Timer5 External Clock Requirements .....	433
Alternate Interrupt Vector Table (AVT) .....	91
Assembler	
MPASM Assembler .....	404

### B

#### Block Diagrams

10-Bit A/D Converter Analog Input Model .....	368
12-Bit A/D Converter .....	352
16-Bit Asynchronous Timer3 and Timer5 .....	207
16-Bit Synchronous Timer2 and Timer4 .....	207

**NOTES:**

## THE MICROCHIP WEB SITE

Microchip provides online support via our WWW site at [www.microchip.com](http://www.microchip.com). This web site is used as a means to make files and information easily available to customers. Accessible by using your favorite Internet browser, the web site contains the following information:

- **Product Support** – Data sheets and errata, application notes and sample programs, design resources, user's guides and hardware support documents, latest software releases and archived software
- **General Technical Support** – Frequently Asked Questions (FAQ), technical support requests, online discussion groups, Microchip consultant program member listing
- **Business of Microchip** – Product selector and ordering guides, latest Microchip press releases, listing of seminars and events, listings of Microchip sales offices, distributors and factory representatives

## CUSTOMER CHANGE NOTIFICATION SERVICE

Microchip's customer notification service helps keep customers current on Microchip products. Subscribers will receive e-mail notification whenever there are changes, updates, revisions or errata related to a specified product family or development tool of interest.

To register, access the Microchip web site at [www.microchip.com](http://www.microchip.com). Under "Support", click on "Customer Change Notification" and follow the registration instructions.

## CUSTOMER SUPPORT

Users of Microchip products can receive assistance through several channels:

- Distributor or Representative
- Local Sales Office
- Field Application Engineer (FAE)
- Technical Support

Customers should contact their distributor, representative or Field Application Engineer (FAE) for support. Local sales offices are also available to help customers. A listing of sales offices and locations is included in the back of this document.

**Technical support is available through the web site at: <http://microchip.com/support>**

## **NOTES:**

---

**Note the following details of the code protection feature on Microchip devices:**

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

**QUALITY MANAGEMENT SYSTEM  
CERTIFIED BY DNV  
= ISO/TS 16949 =**

*Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEELOQ® code hopping devices, Serial EEPROMS, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.*
